VARIATIONAL DERIVATION OF MODAL-NODAL  
FINITE DIFFERENCE EQUATIONS IN  
SPATIAL REACTOR PHYSICS

by

PATRICK G. BAILEY

Submitted to the Department of Nuclear Engineering on July 18, 1972,  
in partial fulfillment of the requirements for the degree of Doctor of  
Philosophy.

ABSTRACT

A class of consistent coarse mesh modal-nodal approximation methods is presented for the solution of the spatial neutron flux in multigroup diffusion theory. The methods are consistent in that they are systematically derived as an extension of the finite element method by utilizing general modal-nodal variational techniques. Detailed subassembly solutions, found by imposing zero current boundary conditions over the surface of each subassembly, are modified by piecewise continuous Hermite polynomials of the finite element method and used directly in trial function forms. Methods using both linear and cubic Hermite basis functions are presented and discussed.

The proposed methods differ substantially from the finite element methods in which homogeneous nuclear constants, homogenized by flux weighting with detailed subassembly solutions, are used. However, both schemes become equivalent when the subassemblies themselves are homogeneous.

One-dimensional, two-group numerical calculations using representative PWR nuclear material constants and 18-cm subassemblies were performed using entire subassemblies as coarse mesh regions. The results indicate that the proposed methods can yield comparable if not superior criticality measurements, comparable regional power levels, and extremely accurate subassembly fine flux structure with little increase of computational effort in comparison with existing coarse mesh methods.

Titles: Professors of Nuclear Engineering

## ACKNOWLEDGMENTS

I would like to express my deep appreciation and sincerest gratitude to Dr. Allan F. Henry whose advice and consultation have been of considerable help during the course of this work. Thanks must also be extended to Dr. Kent F. Hansen, who reviewed the final manuscript and provided many beneficial discussions and programming assistance.

It has also been a privilege to have known and worked with the late Dr. T. J. Thompson, whose untimely death was a great loss to the nation as well as to the department at M.I.T., and Dr. Elias P. Gyftopoulos. Their insistence on high standards of education and quality as well as clarity of expression will continue to remain with me always.

Fellowship support by the U.S. Atomic Energy Commission is also gratefully acknowledged. The work was performed under USAEC Contract AT (30-1) - 3903. All computations were performed on IBM 360/65 and 370/155 computers at the M.I.T. Information Processing Center.

Special appreciation is extended to my wife, Alice, whose patience and understanding have provided immeasurable support throughout the course of this work.

Finally, special thanks are expressed to Mrs. Mary Bosco, who has once again demonstrated her expert ability as a superb technical typist.

## Chapter 1

### INTRODUCTION

#### 1.1 Preface

The large variety of approximation methods and techniques used in computational reactor analysis and simulation has caused the area of numerical reactor physics to become one of the most exciting areas in applied nuclear reactor physics today. The application of numerical analysis is most important in two phases of reactor design; feasibility studies and safety analysis. The primary consideration of the reactor physicist has been and must continue to be the safety of the reactor during and after any foreseeable nuclear accident. A realistic safety analysis can be obtained only if all the physical processes occurring within the reactor can be adequately described and related. Since all of these processes can be shown to be dependent upon the neutron density distribution throughout the reactor core, a detailed solution of the spatial neutron flux is vital.<sup>1</sup>

The dynamic characteristics of a reactor strongly depend upon the spatial approximation and solution of the neutron flux. Approximation methods utilizing gross averaging of the flux near localized strong absorption and production regions, such as cruciform control rods or small water channels, can lead to inaccurate results. Large errors may result from the use of such methods in spatial kinetics problems such as depletion and xenon oscillation calculations. Much attention has therefore been focused upon approximation methods

which can obtain detailed spatial neutron flux distributions within large reactor cores.

The Boltzmann neutron transport equation<sup>2</sup> is considered to be a sufficiently detailed description of the physical processes occurring within a nuclear reactor, and naturally is most difficult to solve. The P-1 and diffusion theory approximations<sup>3</sup> greatly simplify the transport equation into more tractable equations which have been found to approximate adequately the flux distributions for most large-core reactors such as PWR, BWR, and LMFBR core geometries. The advent of high speed digital computers has enabled widespread use of diffusion theory because of its simple mathematical form and straightforward numerical solution techniques inherent with its use.

The treatment of the spatial approximation in diffusion theory is the primary concern of this report. There is in existence an increasingly abundant variety of such approximation methods currently in use. Fine mesh methods,<sup>4</sup> for example, can yield very accurate results through the use of extremely large numbers of unknowns. However, such methods may well exceed the storage capacity of present day computers, as well as being exceedingly costly. Coarse mesh methods and particularly synthesis techniques,<sup>5</sup> on the other hand, have recently become attractive as the number of unknowns can be drastically reduced, although the accuracy of many of these methods is in doubt.

The purpose of this report is twofold: first, to present the general development of variational approximation methods used to derive

difference approximations to the neutron diffusion equation; and second, to extend this development in order to develop systematically a class of consistent coarse mesh approximation methods which can approximate accurately the detailed spatial neutron flux and can also be easily incorporated into present day computer codes. As this report will deal only with the spatial approximation, the inclusion of time dependence will be set aside for future study.

## 1.2 The Time-Independent, Multigroup Diffusion Theory Equations

The energy discretized multigroup P-1 approximation to the Boltzmann neutron transport equation excluding time dependence can be written in standard group notation for each energy group  $g$  as follows:<sup>3</sup>

$$\underline{j}_g(r) + D_g(r) \underline{\nabla} \phi_g(r) = 0 \quad (1.1a)$$

$$\underline{\nabla} \cdot \underline{j}_g(r) + \Sigma_g(r) \phi_g(r) - \sum_{\substack{g'=1 \\ g' \neq g}}^G \Sigma_{gg'}(r) \phi_{g'}(r) = \frac{1}{\lambda} \chi_g \sum_{g'=1}^G \nu \Sigma_{fg'}(r) \phi_{g'}(r) \quad (1.1b)$$

where the group index  $g$  runs from the highest energy group, 1, to the lowest energy group,  $G$ . The symbols and notation used throughout this report are summarized in Appendix A. Equations 1.1 are the standard P-1 equations which relate the vector neutron current  $\underline{j}_g(r)$  for each energy group  $g$  with the scalar neutron flux  $\phi_g(r)$ . The current may be eliminated via Fick's law, Eq. 1.1a, in order to obtain the multigroup diffusion equation:

$$-\underline{\nabla} \cdot D_g(r) \underline{\nabla} \phi_g(r) + \Sigma_g(r) \phi_g(r) - \sum_{\substack{g'=1 \\ g' \neq G}}^G \Sigma_{gg'}(r) \phi_{g'}(r) = \frac{1}{\lambda} \chi_g \sum_{g'=1}^G \nu \Sigma_{fg'}(r) \phi_{g'}(r) \quad (1.2)$$

Equation 1.2 can be written in operator matrix notation as

$$-\underline{\nabla} \cdot \mathbb{D}(\mathbf{r}) \underline{\nabla} \Phi(\mathbf{r}) + [\mathbb{M}(\mathbf{r}) - \mathbb{T}(\mathbf{r})] \Phi(\mathbf{r}) = \frac{1}{\lambda} \mathbb{B}(\mathbf{r}) \Phi(\mathbf{r}) \quad (1.3)$$

where  $\mathbb{D}$ ,  $\mathbb{M}$ ,  $\mathbb{T}$ , and  $\mathbb{B}$  are  $G \times G$  group matrices defined by

$$\mathbb{D}(\mathbf{r}) = \text{Diag}[D_1(\mathbf{r}) \dots D_g(\mathbf{r}) \dots D_G(\mathbf{r})] \quad (1.4a)$$

$$\mathbb{M}(\mathbf{r}) = \text{Diag}[\Sigma_1(\mathbf{r}) \dots \Sigma_g(\mathbf{r}) \dots \Sigma_G(\mathbf{r})] \quad (1.4b)$$

$$\mathbb{T}(\mathbf{r}) = \begin{bmatrix} 0 & -\Sigma_{12}(\mathbf{r}) & \dots & -\Sigma_{1G}(\mathbf{r}) \\ -\Sigma_{21}(\mathbf{r}) & 0 & \dots & -\Sigma_{2G}(\mathbf{r}) \\ \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ -\Sigma_{G1}(\mathbf{r}) & -\Sigma_{G2}(\mathbf{r}) & \dots & 0 \end{bmatrix} \quad (1.4c)$$

$$\mathbb{B}(\mathbf{r}) = \begin{pmatrix} \chi_1 \\ \vdots \\ \vdots \\ \chi_G \end{pmatrix} \begin{bmatrix} \nu \Sigma_{f1}(\mathbf{r}) & \dots & \nu \Sigma_{fG}(\mathbf{r}) \end{bmatrix} \quad (1.4d)$$

and  $\Phi(\mathbf{r})$  is the group flux vector

$$\Phi(\mathbf{r}) = \text{Col}[\phi_1(\mathbf{r}) \dots \phi_G(\mathbf{r})] \quad (1.4e)$$

In problems where no upscattering is present,  $\Sigma_{gg'}(\mathbf{r}) = 0$  for  $g < g'$ , and  $\mathbb{T}$  becomes  $G \times G$  lower triangular.

It is also convenient to define the group current vector  $\underline{J}(\mathbf{r})$

$$\underline{J}(\mathbf{r}) = \text{Col}[\underline{j}_1(\mathbf{r}) \dots \underline{j}_G(\mathbf{r})] \quad (1.4f)$$

and the  $G \times G$  group absorption, scattering and production matrix  $\underline{\Lambda}(\mathbf{r})$

$$\underline{\Lambda}(\mathbf{r}) = \mathbb{M}(\mathbf{r}) - \mathbb{T}(\mathbf{r}) - \frac{1}{\lambda} \mathbb{B}(\mathbf{r}) \quad (1.4g)$$

Equations 1.1 and 1.2 may then be written simply as

$$\underline{J}(\mathbf{r}) + \underline{D}(\mathbf{r}) \underline{\nabla} \Phi(\mathbf{r}) = 0 \quad (1.5a)$$

$$\underline{\nabla} \cdot \underline{J}(\mathbf{r}) + \underline{\Lambda}(\mathbf{r}) \Phi(\mathbf{r}) = 0 \quad (1.5b)$$

and

$$-\underline{\nabla} \cdot \underline{D}(\mathbf{r}) \underline{\nabla} \Phi(\mathbf{r}) + \underline{\Lambda}(\mathbf{r}) \Phi(\mathbf{r}) = 0 \quad (1.6)$$

respectively. These forms of the group diffusion equations will be used throughout this report. The boundary conditions on  $\Phi(\mathbf{r})$  are of the homogeneous Neumann or Dirichlet type,<sup>6</sup> while the normal component of the current  $\underline{J}(\mathbf{r})$  is required to be continuous across all internal interfaces.

### 1.3 Solution Methods

All of the solution methods which can be employed in order to obtain approximate solutions to the time-dependent, multigroup diffusion equations may be conveniently classified as belonging in the area of either nodal analysis or modal analysis, or a combination of the two: modal-nodal analysis. The principal concept in each of these analyses is that the neutron flux, a continuous function of many variables, may be approximated as a set of unknown coefficients and/or functions of possibly fewer variables. The ultimate goals of such approximation methods are to produce easily solvable coupled equations which relate the unknowns to each approximation and yield results of acceptable accuracy at a low cost. Various commonly used methods and their drawbacks are discussed below.

### 1.3.1 Nodal Methods

Nodal methods involve the local approximation of an average flux at points called nodes, where each node represents a distinct region within the reactor in which the average flux is defined. An ordered set of nodes connected by a grid of mesh lines is then used to approximate the spatial flux behavior. The accuracy of such methods is generally governed by the internodal coupling or neutron current approximation inherent in each method.

#### A. Conventional Finite Difference Equations

The common finite difference equations used in diffusion theory can be derived using Taylor series expansion, variational techniques, or box integration methods about each spatial node.<sup>7</sup> The second-order diffusion term at each node is replaced by three-point difference equations relating consecutive nodes in each spatial direction. The resulting band-structured matrix equations exhibit many advantageous mathematical properties and can be solved with the use of simple solution algorithms.

The attractiveness of these difference equations is further enhanced by the fact that, for properly posed problems (including proper boundary conditions), the approximation can be shown to converge to the solution of the differential equation as the mesh size approaches zero. Also, the accuracy of the approximation can be shown to be in general of order  $\theta(h)$ ,<sup>8</sup> thus error estimates for the approximation are available. It is for these reasons that these equations are frequently invoked as "exact" solutions to diffusion equation problems. The main disadvantage, however, is that, as the

number of nodes increases, the amount of labor and cost involved in order to obtain an accurate solution increases geometrically. A point of diminishing returns is then quickly reached where further accuracy is prohibitively expensive. Another disadvantage is that any known physical insight or *a priori* detailed flux behavior cannot be used with this approximation.

A formal derivation of the conventional difference equations is given in section 2.3 of Chapter 2.

### B. Gross Coupling Models

In gross coupling or coarse mesh nodal techniques an attempt is made to decrease drastically the number of nodes needed for solution without significantly decreasing solution accuracy. Many such methods have been proposed by postulating various forms of neutronic coupling or communication interaction between nodes.

#### 1. Phenomenological Model<sup>9,10,11</sup>

From a physical viewpoint, the reactor can be divided into several distinct regions, each represented by a node located somewhere in that region. Equations of balance relating state variables of interest (average neutron flux, regional power, etc.) can then be written for each region and between region nodes. Internodal coupling is governed by a set of coefficients, say  $p_{ij}$ , which may account for the number of neutrons born in region  $i$  which appear in region  $j$ . A set of algebraic equations can then be written which describe the coupled core dynamics of the nodal interactions.

The principal drawback of such methods lies in the definition of the interaction parameters  $p_{ij}$ . Although the describing equations of the phenomenological model can be directly formulated from diffusion theory,<sup>12</sup> the method of calculating the coefficients  $p_{ij}$  remains unclear. However, the physical simplicity of this model has made it very appealing in coupled kinetics methods development. Much of the work in this field is based on deriving approximations which reduce to this simple conceptual model.

## 2. Effective D/L Coupling<sup>13</sup>

These methods are very similar to finite difference approximations in that the structural forms of the resulting difference equations are identical. In order to compensate for the use of large internodal mesh spacing, the reactor constants, and the diffusion coefficients in particular, may be altered so that they correspond in an average sense to those obtained from a fine mesh calculation.<sup>14</sup> In this way it is hoped that the gross internodal coupling will be sufficiently improved to compensate for the large mesh spacings.

It has been shown that such methods can indeed improve internodal coupling for large mesh regions; however, the results are generally not satisfactory since the coupling constants are dependent in an unpredictable way on changes in the properties of the nodes.

## 3. Fission Source Coupling<sup>15</sup>

The assumption that the reactor flux can be separated into partial region fluxes due to nodal fission sources permits a consistent derivation of nodal coupled kinetics equations from multigroup

diffusion theory. Fission modes can be found from detailed flux solutions which are then used to account for internodal coupling. This method gives reasonably accurate results for fast and thermal reactor transients, although the number of nodes necessary to achieve an accurate solution must increase as the form of the spatial flux becomes more detailed.

#### 4. Multichannel Coupling<sup>16</sup>

By partitioning the reactor into regions called channels and allowing only adjacent channel-to-channel interactions, coupling coefficients  $p_{ij}$  can be found which represent the net leakage of neutrons from channel  $i$  into channel  $j$  in terms of the corresponding averaged channel fluxes. The coupling coefficients can be calculated using diffusion theory or variational techniques which yield the diffusion equations as stationary conditions. This model is appealing in that it can be shown to reduce to the conventional difference equations when a regular grid of small channel regions is used.

The above examples of gross coupling models are generally unsatisfactory because they require the use of average fluxes defined within large regions of the reactor. More acceptable results are obtained by utilizing known or *a priori* detailed spatial flux shapes in the regions in the approximation method.

#### 1.3.2 Modal Methods<sup>17</sup>

Modal methods imply an extensive rather than local approximation to the spatial neutron flux. In general the flux is represented by a combination of known functions defined over the regions of interest

with unknown functions as mixing coefficients. Depending upon the approximation employed, relationships among these coefficients can be derived which are hopefully simpler to solve than the original equation.

#### A. Helmholtz Modes<sup>18</sup>

The diffusion equation for a completely homogeneous reactor formally has an infinite solution set of eigenvalues and corresponding orthogonal eigenfunctions, called Helmholtz modes, which satisfy the homogeneous boundary conditions. For the general case of a heterogeneous reactor, the spatially dependent flux can be approximated as a linear combination of these modes. The major difficulty with this approach is that a large number of modes is required in order to approximate the solution flux, and thus the appeal for this simplistic modal approach is quickly lost.

#### B. Lambda<sup>19</sup> and Omega Modes<sup>20</sup>

Although included in the class of modal approximations, these methods require the use of known spatial solutions for time-dependent analysis. Lambda modes belong to the set of detailed flux solutions of the time-independent diffusion equations which correspond to different lambda eigenvalues.

A set of detailed flux solutions can also be found from the time-dependent diffusion equations by allowing the time-dependent flux to be separable and given in the form  $e^{\omega t}$ . The solutions of the resulting equations, called  $\omega$  modes, correspond to different omega eigenvalues.

Both of these methods have successfully been used in the transient analysis of coupled nodal kinetics.

### C. Synthesis Methods<sup>5,21</sup>

The use of synthesis techniques for the derivation of modal approximations is the most exciting and fastest growing area of reactor analysis methods development. This can be attributed to the fact that all diffusion theory approximation schemes, both modal and nodal, and those including time dependence, can be ultimately derived from one single variational principle. Each approximation scheme is therefore dependent solely upon the form of the trial functions used to represent the flux, current, and weighting functions (or adjoint functions) in the synthesis procedure. The outstanding advantage of the synthesis method is that knowledge of *a priori* detailed flux shapes or other physical insights can be incorporated directly into the approximation method.

#### 1. Multichannel Synthesis<sup>22</sup>

This method may be viewed as a modal extension of the multichannel gross coupling method. Assuming the flux to be separable in its variables  $(x, y, z)$ , the number of unknowns can be reduced by specifying detailed flux shapes in any dimension. A common example assumes that in each channel,  $k$ , of the reactor the flux trial function,  $U_k(x, y, z)$ , can be expressed as the product of a known transverse flux,  $\psi_k(x, y)$ , with an unknown spatially dependent axial flux,  $\rho_k(z)$ , as:

$$U_k(x, y, z) = \rho_k(z) \psi_k(x, y) \quad (1.7)$$

The specification of the flux in two dimensions reduces the problem to an approximation involving only one dimension. If, however, the flux is approximated by a full spatial solution times an unknown constant,

$$U_k(x, y, z) = F_k \psi_k(x, y, z) \quad (1.8)$$

the method reduces to an approximation similar to the multichannel nodal method. Figure 1.1 illustrates the resulting flux shape characteristics of such a method for the one-dimensional case.

The major disadvantage of these multichannel synthesis methods lies in the fact that in general the flux is discontinuous at channel interfaces.<sup>23,24</sup> Therefore the adjacent channel coupling currents, which then must be continuous across these interfaces,<sup>†</sup> are defined in terms of averaged channel fluxes. Although these methods can produce detailed flux distributions in each channel, their accuracy appears to be not much better than nodal multichannel methods because of the averaged gross neutronic coupling requirements inherent in these methods.<sup>25</sup>

## 2. Overlapping Multichannel Synthesis<sup>26,27</sup>

The interchannel neutronic coupling can be improved by requiring that the flux trial functions be continuous across channel interfaces. This can be accomplished by modulating the known expansion functions,  $\psi_k$ , by piecewise continuous normalized polynomial functions,  $p_k$ , which are nonzero only within coupled channels

---

<sup>†</sup>Variational techniques used with diffusion theory in general do not allow the flux and current to be simultaneously discontinuous. Further clarification is given in section 2.2 of Chapter 2.

Figure 1.1. Illustration of One-Dimensional Multichannel Synthesis

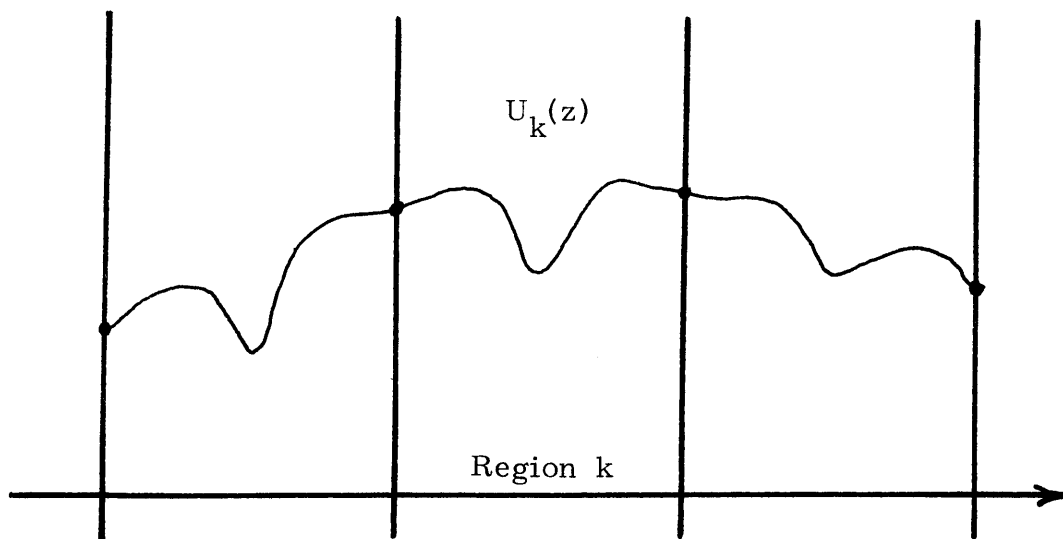

Figure 1.2. Illustration of One-Dimensional Overlapping Multichannel Synthesis

of interest, providing the expansion functions are continuous over all channels for which the corresponding polynomial functions are nonzero. Such polynomials are required to be normalized to unity at the coupling interface and zero along the external boundary of the channels in order to preserve flux trial function continuity.

In one dimension represented by the continuous variable  $z$  and  $K$  mesh regions bounded by the nodes  $z_k$  where  $k = 1$  to  $K+1$ , for example, the simple linear functions

$$p_k(z) = \begin{cases} \frac{z - z_{k-1}}{z_k - z_{k-1}} & z_{k-1} \leq z \leq z_k \\ \frac{z_{k+1} - z}{z_{k+1} - z_k} & z_k \leq z \leq z_{k+1} \\ 0 & \text{otherwise} \end{cases} \quad (1.9)$$

satisfy these conditions. The flux can then be approximated as

$$U(z) = \sum_{k=1}^K F_k p_k(z) \psi_k(z) \quad (1.10)$$

where the set of  $F_k$ 's are the unknowns of the method. The resulting flux shape characteristics of this approximation are illustrated in Figure 1.2.

Approximations based on this synthesis method are dependent upon the class of overlapping polynomial functions used as well as the form of the current trial functions employed. The form of the current is extremely important in that it specifies the coupling interaction between regions and in this sense governs the usefulness and accuracy

of the approximation. Work performed with this method to date has used current trial functions of a form similar to those of the flux trial function. Although the results of these investigations have been encouraging, such methods do not reduce to more simple known approximation methods. In addition, the band-structured matrix equations which arise from the use of such methods do not exhibit mathematical properties desired of such approximation schemes and may be difficult and costly to solve.

### 1.3.3 Modal-Nodal Methods

Approximation methods have also been developed in which the flux has a known extensive definition, or shape, and the unknowns are local flux values averaged in accordance with their corresponding extensive definition. Such modal-nodal methods retain all of the advantages of modal methods while generally reducing the number of unknowns and producing matrix equations which have desirable mathematical properties for numerical approximation and solution.

The finite element method is the best example of a modal-nodal approximation. Greater accuracy than that of conventional difference techniques can be obtained by allowing the flux in each region of interest to be represented as a polynomial which is continuous at region interfaces. The forms of the flux approximations and the resulting difference equations which arise from the use of the finite element method are described in detail in section 2.3 of Chapter 2.

The purpose of this report is to present an original and consistent class of modal-nodal coarse mesh approximation methods which retain given or known detailed flux structure within the regions of interest, while providing detailed neutronic coupling between adjacent regions. These methods are consistent in that they are derived from a general variational principle and are a systematic extension of the finite element method as applied to diffusion theory reactor analysis.

For purposes of simplicity, the methods will be developed for the case of one-dimensional, time-dependent, multigroup diffusion theory, although it is expected that these methods can be extended to the general spatially dependent kinetics problem with relative ease.

The remainder of this report is organized as follows. Chapter 2 summarizes the use of variational principles and synthesis techniques in time-independent diffusion theory. The difference equations of the finite element methods applied in one dimension are derived using modal-nodal trial function forms in order to illustrate the use of these techniques. The forms of the proposed approximation methods are given in Chapter 3. The resulting finite difference equations are presented and boundary conditions discussed for approximation methods involving both linear and cubic Hermite basis functions. The numerical properties of the resulting matrix equations, as well as their numerical solution scheme, and useful programming techniques are discussed in Chapter 4. Chapter 5 presents results of the proposed methods for four representative one-dimensional PWR configurations, and compares the results with those of coarse mesh finite element methods. Finally, Chapter 6 presents conclusions and recommendations as well as comments concerning the possibility of extending the proposed methods to multidimensional geometries.

## Chapter 2

VARIATIONAL DERIVATION OF FINITE DIFFERENCE  
APPROXIMATIONS IN TIME-INDEPENDENT  
MULTIGROUP DIFFUSION THEORY

The application of variational calculus to the describing equations of physical systems is perhaps the most general and powerful method of obtaining approximate solutions in mathematical physics. Variational methods seek to combine known "trial functions" into approximate solutions through the use of a variational functional which characterizes the equations of the system.

Essentially, variational methods consist of first finding a characteristic functional whose first-order variation when set to zero yields the describing equations of the system as its Euler equations. A class of trial functions, given in terms of known functions and unknown coefficients (or functions), is then chosen to approximate the solutions of the describing equations. These trial functions are then substituted into the variational functional, and its first variation is set to zero. Allowing arbitrary variations in all of the trial function unknowns results in a set of relationships among the unknowns. These relationships when solved then yield the "best" obtainable approximate solution within the space of trial functions given.

Variational methods can be thought of as a class of weighted residual methods since "weighting functions" appear in the functional and in the equations that result from setting the first variation of the functional to zero. The weighting functions are determined by the

form of the functional itself; or equivalently, by the set of Euler equations selected to describe the system. In non-self adjoint problems, the adjoint equations are generally included in the set of Euler equations. The inclusion of corresponding "adjoint trial functions" in the functional results in adjoint weighting in the variation equations and allows greater approximation flexibility of the variational method.

## 2.1 Calculus of Variations Applied to Diffusion Theory

The time-independent multigroup diffusion equations as given by Eq. 1.3 can be written as

$$\mathbb{H} \Phi = \frac{1}{\lambda} \mathbb{B} \Phi \quad (2.1a)$$

where

$$\mathbb{H} = -\underline{\nabla} \cdot \mathbb{D} \underline{\nabla} + \mathbb{M} - \mathbf{T} \quad (2.1b)$$

Since the multigroup diffusion equations are not self-adjoint, it is convenient to introduce the adjoint diffusion equations

$$\mathbb{H}^* \Phi^* = \frac{1}{\lambda} \mathbb{B}^* \Phi^* \quad (2.2a)$$

where  $\mathbb{H}^*$  and  $\mathbb{B}^*$  are the adjoint operators corresponding to  $\mathbb{H}$  and  $\mathbb{B}$ , respectively, and are defined as:<sup>3</sup>

$$\mathbb{H}^* = \mathbb{H}^T = -\underline{\nabla} \cdot \mathbb{D} \underline{\nabla} + \mathbb{M} - \mathbf{T}^T \quad (2.2b)$$

$$\mathbb{B}^* = \mathbb{B}^T \quad (2.2c)$$

since  $\mathbb{D}$  and  $\mathbb{M}$  are diagonal.  $\Phi^*$  is the group adjoint flux vector, or importance vector, which must obey the same boundary conditions as  $\Phi$ .

The exact solutions  $\Phi(r)$  and  $\Phi^*(r)$  of the diffusion equations and the adjoint diffusion equations can be approximated by flux and adjoint flux trial functions denoted as  $U(r)$  and  $U^*(r)$  using a variational functional of the form

$$\mathcal{F}_1 [U, U^*] = \frac{1}{\lambda} = \frac{\int_{\mathbf{R}} U^{*\text{T}} \mathbf{H}U \, dr}{\int_{\mathbf{R}} U^{*\text{T}} \mathbf{B}U \, dr} \quad (2.3)$$

where it is assumed that the group-theory flux trial function vectors  $U^*$  and  $U$  as well as the group current vectors  $\mathbf{D}\nabla U^*$  and  $\mathbf{D}\nabla U$  are everywhere continuous, and that  $U^*$  and  $U$  vanish outside the reactor region  $\mathbf{R}$ . Allowing arbitrary trial function variations, denoted by  $\delta U^*$  and  $\delta U$ , making  $\mathcal{F}_1$  stationary first with respect to  $U^*$  and then with respect to  $U$  results<sup>29</sup> in the following equations:

$$\int_{\mathbf{R}} \delta U^{*\text{T}} \left[ \mathbf{H}U - \frac{1}{\lambda} \mathbf{B}U \right] \, dr = 0 \quad (2.4a)$$

$$\int_{\mathbf{R}} \left[ U^{*\text{T}} \mathbf{H} - \frac{1}{\lambda} U^{*\text{T}} \mathbf{B} \right] \delta U \, dr = 0 \quad (2.4b)$$

The above equations, containing the desired Euler equations, are the equations upon which the approximation method is based.

A significant characteristic of this approximation form is the property of exact solution reproduction. Although general choices of the trial functions  $U$  and  $U^*$  result in approximate eigenvalues which may differ substantially from the exact solution eigenvalue, the exact solutions, when chosen within the given class of trial functions, are yielded as the result of the approximation along with the exact solution eigenvalue.

The nature of the above approximation depends solely upon the forms of the flux trial functions given. Each trial function can be defined in terms of unknown coefficients (or functions) and known functions. Independent variation of the unknown coefficients of the adjoint trial function in Eq. 2.4a will yield the "best" flux solution obtainable for that class of flux and adjoint flux trial functions given. The corresponding "best" adjoint flux solution can be found in an analogous manner using Eq. 2.4b. These techniques are illustrated in the next section.

Another functional incorporating the flux and adjoint flux diffusion equations can be defined as

$$\mathcal{F}_2[U^*, U] = \int_{\mathbf{R}} U^{*T} [HU - \frac{1}{\lambda} BU] dr \quad (2.5)$$

Although the forms of the above functionals differ, it can be shown that both produce the same variation equations, Eqs. 2.4, when made stationary. The form of  $\mathcal{F}_2$  and its first variation are much less complex than the form and first variation of  $\mathcal{F}_1$ . For these reasons, functionals of the form of  $\mathcal{F}_2$  will be used in this report.

## 2.2 Discontinuous Trial Functions

The addition of discontinuous flux trial functions into the class of allowable trial functions for use in diffusion theory variational methods greatly enhances and generalizes the versatility of such methods.<sup>25</sup> However, special provisions must be made in the approximation method itself in order that such trial functions can be properly used.<sup>23, 24, 30</sup> In order to account for the discontinuities in the flux (and in general also the current) trial functions, it is necessary to

include special terms specifying continuity conditions directly within the approximation method. This can be accomplished through the use of a variational functional whose Euler equations include the P-1 equations and continuity conditions for both flux and current. A general functional of this type which allows discontinuous flux, current, and adjoint trial functions can be derived from previous work<sup>30,31</sup> and is given as follows:

$$\begin{aligned}
\mathcal{F}[U^*, U, \underline{V}^*, \underline{V}, \alpha, \beta] = & \int_R \{ U^{*\text{T}} [\underline{\nabla} \cdot \underline{V} + \underline{\Delta} U] + \underline{V}^{*\text{T}} \cdot [\underline{\nabla} U + \underline{D}^{-1} \underline{V}] \} dr \\
& + \int_{\Gamma} \hat{n} \cdot \{ [U_+^{*\text{T}} \alpha + U_-^{*\text{T}} (I - \alpha)] (\underline{V}_+ - \underline{V}_-) \\
& + [\underline{V}_+^{*\text{T}} \beta + \underline{V}_-^{*\text{T}} (I - \beta)] (U_+ - U_-) \} ds
\end{aligned} \tag{2.6}$$

where  $U^*$ ,  $U$ ,  $\underline{V}^*$ , and  $\underline{V}$  are the group flux and group current approximations to  $\Phi^*$ ,  $\Phi$ ,  $\underline{J}^*$ , and  $\underline{J}$ , respectively, and where the first integral extends over the volume  $R$  of the reactor and the second extends over all interior surfaces  $\Gamma$  upon which discontinuities are defined.  $\hat{n}$  is the unit vector perpendicular to interior surfaces, and quantities evaluated on sides of surfaces toward which  $\hat{n}$  is pointing are denoted with the subscript (+). Quantities evaluated on sides of surfaces from which  $\hat{n}$  is pointing are denoted with the subscript (-).  $\alpha$  and  $\beta$  are in general  $G \times G$  undefined variable matrices, and  $I$  is in general a  $G \times G$  unit matrix, which allow a general treatment of the discontinuities.

The restrictions generally imposed upon trial functions for use in functionals of this type are the following:

1. The trial functions must be piecewise continuous.
2. The trial functions  $\underline{U}$  and  $\underline{V}^*$  as well as  $\underline{U}^*$  and  $\underline{V}$  are not allowed to be discontinuous at the same point.
3. The components of  $\underline{U}^T \underline{V}^*$  and  $\underline{U}^{*T} \underline{V}$  normal to the exterior surface of the reactor must vanish.

Due to restriction 2, the general quantities  $\alpha$  and  $\beta$  always cancel and are never used within these approximation methods.

The first variation of  $\mathcal{F}$  can be found in a straightforward manner, and can be simplified to the following form which indicates the desired P-1 and adjoint P-1 equations and the trial function continuity conditions as Euler equations:

$$\begin{aligned}
\delta\mathcal{F} = & \int_{\mathbf{R}} \{ \delta\underline{U}^{*T} [\underline{\nabla} \cdot \underline{V} + \underline{\Lambda}\underline{U}] + \delta\underline{V}^{*T} \cdot [\underline{\nabla}\underline{U} + \underline{\mathbf{D}}^{-1}\underline{V}] \\
& + [-\underline{\nabla}\underline{U}^{*T} + \underline{V}^{*T} \underline{\mathbf{D}}^{-1}] \cdot \delta\underline{V} + [-\underline{\nabla} \cdot \underline{V}^{*T} + \underline{U}^{*T} \underline{\Lambda}] \delta\underline{U} \} d\mathbf{r} \\
& + \int_{\Gamma} \hat{\mathbf{n}} \cdot \{ \delta\underline{U}^{*T} (\underline{V}_+ - \underline{V}_-) + \delta\underline{V}^{*T} (\underline{U}_+ - \underline{U}_-) \\
& \quad + (\underline{U}_-^* - \underline{U}_+^*)^T \delta\underline{V} + (\underline{V}_-^* - \underline{V}_+^*) \delta\underline{U} \} ds
\end{aligned} \tag{2.7}$$

In most applications, only approximations to the flux and current solutions are desired. In such instances variations in only the adjoint trial functions need be taken. Setting the first variation of  $\mathcal{F}$  equal to zero under these conditions and imposing the above trial function restrictions results in the following variation equation for flux and current approximations:

$$\int_{\mathbf{R}} \{ \delta \underline{U}^{*\text{T}} [\underline{\nabla} \cdot \underline{V} + \underline{\Lambda} \underline{U}] + \delta \underline{V}^{*\text{T}} \cdot [\underline{\nabla} \underline{U} + \underline{\mathbb{D}}^{-1} \underline{V}] \} d\mathbf{r}$$

$$+ \int_{\Gamma} \hat{\mathbf{n}} \cdot \{ \delta \underline{U}^{*\text{T}} (\underline{V}_+ - \underline{V}_-) + \delta \underline{V}^{*\text{T}} (\underline{U}_+ - \underline{U}_-) \} ds = 0 \quad (2.8)$$

The above approximation can also be expressed independently of adjoint trial functions. If the adjoint trial functions are defined as

$$\underline{U}^* = \underline{U} \quad (2.9a)$$

$$\underline{V}^* = -\underline{V} \quad (2.9b)$$

then Eq. 2.8 reduces to the Rayleigh-Ritz Galerkin method, a weighted residual method based upon flux weighting.

Regardless of the choice of weighting, the variation equations can be further simplified for those approximation methods which require the currents to obey explicitly Fick's laws:

$$\underline{V} = -\underline{\mathbb{D}} \underline{\nabla} \underline{U} \quad (2.10a)$$

$$\underline{V}^* = +\underline{\mathbb{D}} \underline{\nabla} \underline{U}^* \quad (2.10b)$$

Under these conditions the variation equations for discontinuous flux and discontinuous current trial functions reduce to

$$\int_{\mathbf{R}} \{ \delta \underline{U}^{*\text{T}} \underline{\Lambda} \underline{U} - \delta \underline{V}^{*\text{T}} \cdot \underline{\mathbb{D}}^{-1} \underline{V} \} d\mathbf{r}$$

$$+ \int_{\Gamma} \hat{\mathbf{n}} \cdot \{ (\delta \underline{U}_-^* - \delta \underline{U}_+^*)^{\text{T}} \underline{V} + \delta \underline{V}^{*\text{T}} (\underline{U}_+ - \underline{U}_-) \} ds = 0 \quad (2.11)$$

If in addition the flux is required to be everywhere continuous, the variation equations reduce to the appealing forms

$$\int_{\mathbf{R}} \{ \delta \underline{U}^{*\text{T}} \underline{\Lambda} \underline{U} - \delta \underline{V}^{*\text{T}} \cdot \underline{\mathbb{D}}^{-1} \underline{V} \} d\mathbf{r} = 0 \quad (2.12a)$$

or equivalently

$$\int_{\mathbf{R}} \{ \delta U^{*T} \mathbf{A} U + (\nabla \delta U^*) \cdot \mathbf{D} (\nabla U) \} dr = 0 \quad (2.12b)$$

Variation equations 2.11 and 2.12 are the approximation equations which are used with the finite element methods and the proposed approximation methods.

### 2.3 The Finite Element Approximation Methods <sup>32, 33</sup>

This section introduces the notation and techniques used in conjunction with the modal-nodal variational analysis of the finite element method approximations in one-dimensional multigroup diffusion theory. These fundamentals are presented in these simple approximations before applying them to the more general proposed approximation method in the next chapter.

The one-dimensional problem is defined by the continuous variable  $z$  and divided into  $K$  adjoining regions which are in general inhomogeneous. Each region  $k$  is bounded by nodes  $z_k$  and  $z_{k+1}$  and has width  $h_k = z_{k+1} - z_k$ . It is convenient to define the dimensionless variable  $x$  within each region  $k$  as

$$x = \frac{z - z_k}{h_k} \quad (2.13a)$$

so that region  $k$  can be described in terms of  $z$  as

$$z_k \leq z \leq z_k + h_k = z_{k+1} \quad (2.13b)$$

or equivalently in terms of  $x$  as

$$0 \leq x \leq 1 \quad (2.13c)$$

for each of the regions  $k, k=1$  to  $K$ . This notation will be used throughout this report.

### 2.3.1 The Conventional Finite Difference Equations

The conventional nodal flux-averaged, three-point, finite difference equations of one-dimensional diffusion theory can be derived from Eq. 2.8 using discontinuous flux and current multigroup column vector trial functions of the following form:<sup>7,8 †</sup>

$$\begin{aligned}
 & \left. \begin{aligned} U(z) &= F_k \\ U^*(z) &= F_k^* \end{aligned} \right\} \begin{cases} \left\{ \begin{aligned} z_{k-1} + \frac{1}{2}h_{k-1} \\ z_1 \text{ if } k=1 \end{aligned} \right\} < z < \left\{ \begin{aligned} z_k + \frac{1}{2}h_k \\ z_{K+1} \text{ if } k=K+1 \end{aligned} \right\}; & k=1 \text{ to } K+1. \\ 0 & \text{ otherwise} \end{cases} \\
 & \left. \begin{aligned} V(z) &= G_k \\ V^*(z) &= G_k^* \end{aligned} \right\} \begin{cases} z_k < z < z_k + h_k; & k = 1 \text{ to } K. \\ 0 & \text{ otherwise} \end{cases}
 \end{aligned} \tag{2.14}$$

The forms of these trial functions are illustrated in Figure 2.1.

Inserting these trial functions into variation equation 2.8 results in the equation

$$\begin{aligned}
 & \delta F_1^{*\text{T}} \left\{ \int_0^{\frac{1}{2}} \Lambda_1 F_1 h_1 dx + G_1 - G_0 \right\} \\
 & + \sum_{k=2}^K \delta F_k^{*\text{T}} \left\{ \int_{\frac{1}{2}}^1 \Lambda_{k-1} F_k h_{k-1} dx + \int_0^{\frac{1}{2}} \Lambda_k F_k h_k dx + G_k - G_{k-1} \right\} \\
 & + \delta F_{K+1}^{*\text{T}} \left\{ \int_{\frac{1}{2}}^1 \Lambda_K F_{K+1} h_k dx + G_{K+1} - G_K \right\} \\
 & + \sum_{k=1}^K \delta G_k^{*\text{T}} \left\{ \int_0^1 D_k^{-1} G_k h_k dx + F_{k+1} - F_k \right\} = 0
 \end{aligned} \tag{2.15}$$

---

<sup>†</sup>Shifting the domain of definition of the trial functions results in other approximation schemes with equivalently averaged nuclear constants.<sup>34</sup>

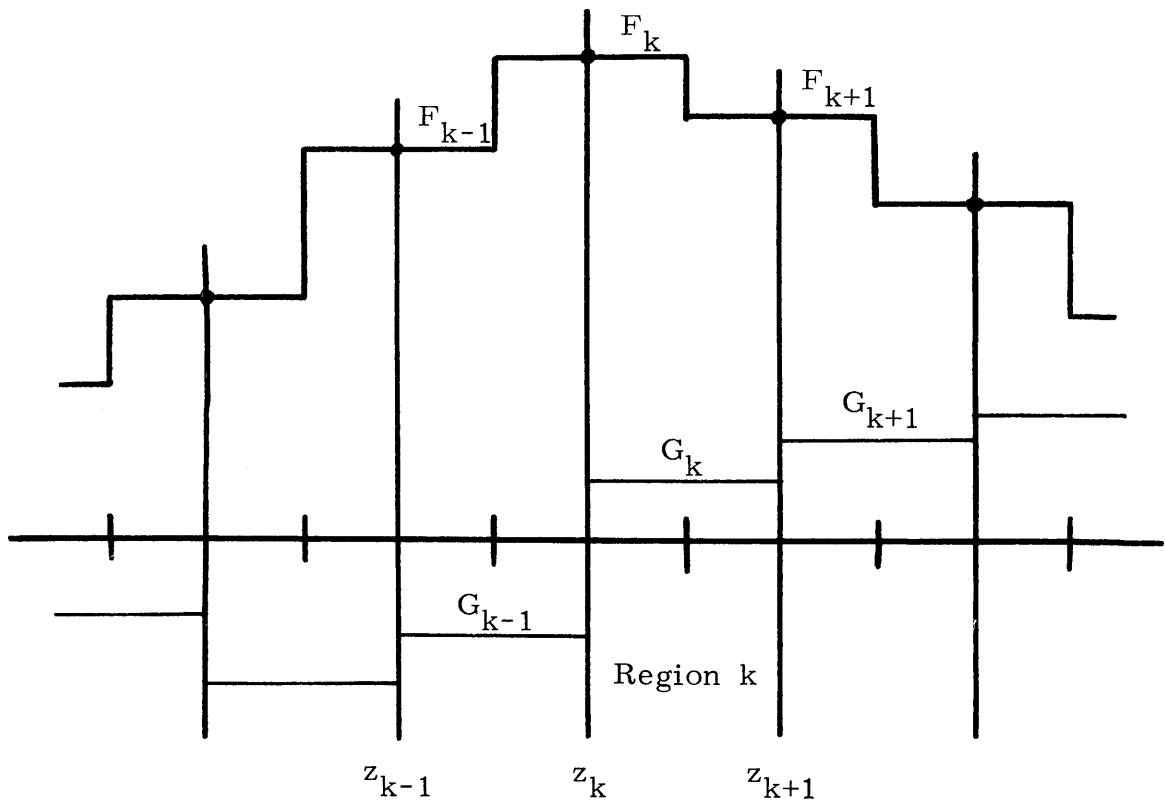

Figure 2.1. Conventional Nodal Finite Difference Approximation Trial Function Forms

Independent variation of all  $F_k^*$  and  $G_k^*$  then results in a system of  $2K+1$  equations and  $2K+3$  unknowns (including  $G_0$  and  $G_{K+1}$ ). The choice of boundary conditions supplies the missing equations. Zero flux boundary conditions can be imposed by setting  $F_1 = F_{K+1} = 0$ , which also requires  $\delta F_1^* = \delta F_{K+1}^* = 0$  thereby eliminating  $G_0$  and  $G_{K+1}$ , and results in a system of  $2K-1$  equations and  $2K-1$  unknowns. Symmetry boundary conditions can be imposed on the left by  $G_0 = -G_1$  and on the right by  $G_{K+1} = -G_K$ , resulting in a system of  $2K+1$  equations and  $2K+1$  unknowns.

Elimination of all  $G_k$ ,  $k = 1$  to  $K$ , results in the standard three-point difference equations

$$b_1 F_1 + c_1 F_2 = 0 \quad (2.16a)$$

$$a_k F_{k-1} + b_k F_k + c_k F_{k+1} = 0; \quad k = 2 \text{ to } K \quad (2.16b)$$

$$a_{K+1} F_K + b_{K+1} F_{K+1} = 0 \quad (2.16c)$$

where Eqs. 2.16a and 2.16c are used for the cases of symmetry boundary conditions. The  $G \times G$  matrix coefficients  $\{a_k, b_k, c_k\}$  are of the form  $A - \frac{1}{\lambda} B$  and are defined assuming homogeneous regional nuclear constants in section 1 of Appendix B. The matrix form of Eqs. 2.16 for the use of zero flux boundary conditions on the left and symmetry on the right is illustrated in Figure 2.2.

### 2.3.2 Multichannel Polynomial Synthesis

The one-dimensional neutron flux  $\Phi_k(z)$  defined as nonzero only within each region  $k$  for each region ( $k=1$  to  $K$ ) can be approximated within each region as a polynomial of order  $N$  by the power series

Figure 2.2. Matrix Form of the Conventional Finite Difference Equations. Boundary conditions chosen are zero flux on the left and symmetry on the right.

$$a_k F_{k-1} + b_k F_k + c_k F_{k+1} = 0; \quad k = 2 \text{ to } K.$$

$$a_{K+1} F_K + b_{K+1} F_{K+1} = 0.$$

where:  $b_k = \beta_k - \frac{1}{\lambda} \epsilon_k; \quad k = 2 \text{ to } K+1.$

$$U_k^{(N)}(z) = \sum_{i=0}^N a_{k,i} x^i \quad (2.17)$$

where the distinction between  $z$  and  $x$  is understood since  $0 \leq x \leq 1$  within each region  $k$ . Such approximations are not useful in diffusion theory because: (1) the resulting matrix equations relating the  $a_{k,i}$ 's contain full matrices similar to Hilbert matrices which may be very difficult to solve; and (2) such matrices are almost always highly singular and may produce numerical instabilities in the solution method. These difficulties can be eliminated by employing polynomials in the trial functions in the following form:

$$U_k^{(N)}(z) \approx \sum_{i=0}^N p_i^{(N)}(x) F_{k+\frac{i}{N}} \quad (2.18)$$

where the  $p_i^{(N)}(x)$  are polynomials in  $x$  of degree  $N$ . This form is convenient because for a particular selection of the  $p_i^{(N)}(x)$  the unknowns  $F_{k+\frac{i}{N}}$  can be defined as the approximate flux solution evaluated at points  $z_i + \frac{i}{N}$  within region  $k$ . For high order approximations,  $i > 0$ , the flux can be made continuous by imposing the following restrictions on  $p_i^{(N)}(x)$ :

$$p_i^{(N)}\left(\frac{\ell}{N}\right) = \begin{cases} 1 & \ell = i \\ 0 & \ell \neq i \end{cases} \text{ for } \ell = 0 \text{ to } N \quad (2.19)$$

The specific polynomial flux approximations of this form through degree  $N=3$  are given below:

$$U_k^{(0)}(x) = F_k \quad (2.20a)$$

$$U_k^{(1)}(x) = (1-x)F_k + xF_{k+1} \quad (2.20b)$$

$$U_k^{(2)}(x) = (1-3x+2x^2)F_k + (4x-4x^2)F_{k+\frac{1}{2}} + (-x+2x^2)F_{k+1} \quad (2.20c)$$

$$U_k^{(3)}(x) = \left(1 - \frac{11}{2}x + 9x^2 - \frac{9}{2}x^3\right)F_k + \left(9x - \frac{45}{2}x^2 + \frac{27}{2}x^3\right)F_{k+\frac{1}{3}} \\ + \left(-\frac{9}{2}x + 18x^2 - \frac{27}{2}x^3\right)F_{k+\frac{2}{3}} + \left(x - \frac{9}{2}x^2 + \frac{9}{2}x^3\right)F_{k+1} \quad (2.20d)$$

An immediate drawback of these approximations lies in the definitions of the corresponding current trial functions. Given a flux polynomial approximation of degree  $N$ , polynomial approximations for the current can be of order zero through  $N$ , and may even be of higher order than the flux approximation. Each set of chosen trial function pairs ultimately results in a characteristic complex band-structured matrix problem which may or may not have desirable numerical solution properties and is usually very difficult to solve.

Such problems can be eliminated by noting that the use of variational analysis attempts to force the current approximation to obey Fick's law. The obvious solution is direct use of Fick's law in the trial function forms

$$V_k(z) = -D_k(z) \frac{d}{dz} U_k(z) \quad (2.21)$$

which results in simple band-structured matrix equations relating only flux unknowns. The use of current polynomial approximations of order  $N-1$  as given in Eqs. 2.20 with flux approximations of order  $N$ , however, does not improve the situation.

The accuracy of these difference equations can be found first by eliminating all non-integer subscripted unknowns, then expanding the resulting three-point difference equations in a Taylor series about

node  $k$ , and comparing results to the exact three-point difference solution known for the one-dimensional case.<sup>7, 35</sup> By comparison of terms containing equal powers of  $h_k$ , it can be shown that the  $N=1$  and  $N=2$  polynomial approximations are accurate to order  $\theta(h^2)$  while the  $N=3$  approximation is accurate to order  $\theta(h^3)$ .

The approximation of a function by a polynomial of order  $N$  leads immediately to the concept of basis functions. The  $N+1$  polynomial functions which multiply the  $N+1$  unknowns in Eq. 2.18 form a basis for the approximation and can be called basis functions. The simplicity of basis functions becomes apparent in an error analysis of the approximation as follows. An approximate solution  $U^{(N)}(z)$  of order  $N$  to the exact one-dimensional solution  $\Phi(z)$  can be expressed as

$$U^{(N)}(z) = \sum_{k=1}^K \Phi(z_k) \Omega_k^{(N)}(z) \quad (2.22a)$$

where  $\Omega_k^{(N)}(z)$  is a basis function of order  $N$  centered about node  $z_k$ . By Taylor series expansion about any node, it can be shown<sup>36</sup> that if  $\Omega_k(z)$  satisfies:

$$\sum_{k=1}^K z_k^\alpha \Omega_k^{(N)}(z) = \left(\frac{z}{h_k}\right)^\alpha \quad \text{for } |\alpha| \leq N \quad (2.22b)$$

then  $U^{(N)}(z)$  is an approximation to  $\Phi(z)$  accurate to order  $\theta(h_k^{N+1})$ .

Basis functions found using Eqs. 2.22 are unique for each  $N$  and generally extend over surrounding regions. The forms of the basis functions for  $N \leq 3$  are summarized below and illustrated in Figure 2.3. Since the following basis functions are symmetric, only the right half,  $z \geq z_k$ , is expressly given.

$$N = 0: \quad \Omega_k^{(0)}(z) = \begin{cases} 1 & z_k \leq z < z_k + \frac{1}{2}h_k \\ 0 & \text{otherwise} \end{cases} \quad (2.23a)$$

$$N = 1: \quad \Omega_k^{(1)}(z) = \begin{cases} (1-x) & z_k \leq z \leq z_{k+1} \\ 0 & \text{otherwise} \end{cases} \quad (2.23b)$$

$$N = 2: \quad \Omega_k^{(2)}(z) = \begin{cases} \frac{3}{4} - x^2 & z_k \leq z \leq z_k + \frac{1}{2}h_k \\ \frac{1}{2} \left( \frac{3}{2} - x \right)^2 & z_k + \frac{1}{2}h_k \leq z \leq z_{k+1} \\ \frac{1}{2} \left( \frac{1}{2} - x \right)^2 & z_{k+1} \leq z \leq z_{k+1} + \frac{1}{2}h_{k+1} \\ 0 & \text{otherwise} \end{cases} \quad (2.23c)$$

$$N = 3: \quad \Omega_k^{(3)}(z) = \begin{cases} \frac{1}{36} (30 - 54x^2 + 28x^3) & z_k \leq z \leq z_{k+1} \\ \frac{1}{36} (4 - 24x + 30x^2 - 11x^3) & z_{k+1} \leq z \leq z_{k+2} \\ \frac{1}{36} (-1 + 3x - 3x^2 + x^3) & z_{k+2} \leq z \leq z_{k+3} \\ 0 & \text{otherwise} \end{cases} \quad (2.23d)$$

where  $0 \leq x \leq 1$  within each region  $k$  in the above cases.

Use of these basis functions results in approximate solutions which are continuous for  $N \geq 1$  and whose derivatives  $dU^{(N)}(z)/dz$  through  $d^{N-1}U^{(N)}(z)/dz^{N-1}$  are also continuous. In high order approximations in diffusion theory, it is advantageous to retain flux and current continuity and employ basis functions defined over two adjacent regions in order to produce three-point difference equations. This can be accomplished in the  $N=3$  approximations with the cubic Hermite basis functions.

Figure 2.3. Basis Functions of Eqs. 2.23 for  $N = 0, 1, 2,$  and  $3$

The above cubic basis function  $\Omega_k^{(3)}(z)$  can be constructed from a combination of either cubic B splines,  $\Omega_k^B(z)$ , or cubic Hermite polynomials,  $\Omega_k^{H_1}(z)$  and  $\Omega_k^{H_2}(z)$ , as follows: <sup>37</sup>

$$\Omega_k^{(3)}(z) = -\frac{1}{6} \Omega_{k-1}^B(z) + \frac{4}{3} \Omega_k^B(z) - \frac{1}{6} \Omega_{k+1}^B(z) \quad (2.24)$$

where:

$$\Omega_k^B(z) = \frac{2}{3} \Omega_k^{H_1}(z) + \frac{1}{6} \Omega_{k+1}^{H_1}(z) - \frac{1}{2} \Omega_{k+1}^{H_2}(z) \quad (2.25)$$

The forms of these cubic B and Hermite polynomials are given below and illustrated in Figures 2.5 and 2.6. Again, only the right half of the functions are expressly given as  $\Omega_k^B$  and  $\Omega_k^{H_1}$  are symmetric, while  $\Omega_k^{H_2}$  is antisymmetric.

$$\Omega_k^B(z) = \begin{cases} \frac{2}{3} - x^2 + \frac{1}{2}x^3 & z_k \leq z \leq z_{k+1} \\ \frac{1}{6}(1-x)^3 & z_{k+1} \leq z \leq z_{k+2} \\ 0 & \text{otherwise} \end{cases} \quad (2.26)$$

$$\Omega_k^{H_1}(z) = \begin{cases} 1 - 3x^2 + 2x^3 & z_k \leq z \leq z_{k+1} \\ 0 & \text{otherwise} \end{cases} \quad (2.27a)$$

$$\Omega_k^{H_2}(z) = \begin{cases} x - 2x^2 + x^3 & z_k \leq z \leq z_{k+1} \\ 0 & \text{otherwise} \end{cases} \quad (2.27b)$$

where again  $0 \leq x \leq 1$  in each region  $k$ .

The fact that the cubic Hermite polynomials form a basis for the cubic basis functions and extend over only two adjacent regions makes them very attractive for use in diffusion theory approximation methods.

$\Omega_k^{H_1}(z)$  and  $\Omega_k^{H_2}(z)$  of Eqs. 2.27

### 2.3.3 The Linear Basis Function Approximation

The group flux trial functions defined as nonzero within each region  $k$  can be expressed in modal-nodal form in terms of linear basis functions as

$$U_k(z) = (1-x)F_k + xF_{k+1} \quad (2.28a)$$

;  $k = 1$  to  $K$ .

$$U_k^*(z) = (1-x)F_k^* + xF_{k+1}^* \quad (2.28b)$$

where  $F_k$  is the approximate group flux column vector at node  $z_k$  and  $0 \leq x \leq 1$  with each region  $k$ . Although the flux trial functions are continuous, the current trial functions defined within each region by Eqs. 2.10 are not, and are given by

$$V_k(z) = \frac{1}{h_k} \mathbb{D}_k(x) [F_k - F_{k+1}] \quad (2.28c)$$

;  $k = 1$  to  $K$ .

$$V_k^*(z) = \frac{1}{h_k} \mathbb{D}_k(x) [F_{k+1}^* - F_k^*] \quad (2.28d)$$

Insertion of these trial function forms into variation equation 2.12a results in the equation

$$\sum_{k=1}^K h_k \int_0^1 \left\{ [(1-x)\delta F_k^* + x\delta F_{k+1}^*]^T \mathbf{\Lambda}_k(x) [(1-x)F_k + xF_{k+1}] + [\delta F_k^* - \delta F_{k+1}^*]^T \frac{1}{h_k} \mathbb{D}_k(x) [F_k - F_{k+1}] \right\} dx = 0 \quad (2.29)$$

Allowing arbitrary variations in all  $F_k^*$  results in a system of  $K+1$  equations and  $K+1$  unknowns which can be written as:

$$b_1 F_1 + c_1 F_2 = 0 \quad (2.30a)$$

$$a_k F_{k-1} + b_k F_k + c_k F_{k+1} = 0 \quad ; \quad k = 2, K. \quad (2.30b)$$

$$a_{K+1} F_K + b_{K+1} F_{K+1} = 0 \quad (2.30c)$$

where the  $G \times G$  matrix coefficients  $\{a_k, b_k, c_k\}$  are of the form  $A - \frac{1}{\lambda} B$  and are defined assuming homogeneous regional nuclear constants in section 2 of Appendix B. Zero flux boundary conditions can be imposed by use of only Eq. 2.30b with  $F_1 = F_{K+1} = 0$ , while symmetry boundary conditions require the use of the other equations as well. The matrix form of these equations for the boundary conditions of zero flux on the left and symmetry on the right is given in Figure 2.6.

### 2.3.4 The Cubic Hermite Basis Function Approximation<sup>38, 39</sup>

The cubic Hermite polynomials can be incorporated into modal-nodal flux trial functions which allow continuous flux and continuous current by defining the flux trial functions within each region  $k$  as

$$U_k(z) = (1-3x^2+2x^3)F_k + (3x^2-2x^3)F_{k+1} \\ + (-x+2x^2-x^3) \frac{\theta}{h_k} \mathbb{D}_k^{-1}(x)G_k + (x^2-x^3) \frac{\theta}{h_k} \mathbb{D}_k^{-1}(x)G_{k+1} \quad (2.31a)$$

$$U_k^*(z) = (1-3x^2+2x^3)F_k^* + (3x^2-2x^3)F_{k+1}^* \\ + (-x+2x^2-x^3) \frac{\theta}{h_k} \mathbb{D}_k^{-1}(x)G_k^* + (x^2-x^3) \frac{\theta}{h_k} \mathbb{D}_k^{-1}(x)G_{k+1}^* \quad (2.31b)$$

where  $k = 1$  to  $K$ .

$F_k$  is again the approximate group flux solution vector at node  $z_k$ , and  $G_k$  is proportional to the approximate group current solution vector at node  $z_k$ . Application of Fick's law defines the current trial functions for each  $k$  as

$$\begin{aligned}
V_k(z) &= \frac{1}{h_k} \mathbb{D}_k(x)(6x-6x^2) [F_{k+1} - F_k] \\
&\quad + (1-4x+3x^2)\theta G_k + (-2x+3x^2)\theta G_{k+1}
\end{aligned} \tag{2.31c}$$

$$\begin{aligned}
V_k^*(z) &= \frac{1}{h_k} \mathbb{D}_k(x)(6x-6x^2) [F_k^* - F_{k+1}^*] \\
&\quad + (-1+4x-3x^2)\theta G_k^* + (2x-3x^2)\theta G_{k+1}^*
\end{aligned} \tag{2.31d}$$

Continuity of flux and current are automatically guaranteed since

$$\begin{aligned}
U_k(0) &= U_{k-1}(h_{k-1}) = F_k \\
U_k^*(0) &= U_{k-1}^*(h_{k-1}) = F_k^* \\
V_k(0) &= V_{k-1}(h_{k-1}) = \theta G_k \\
V_k^*(0) &= V_{k-1}^*(h_{k-1}) = -\theta G_k^* \dagger
\end{aligned} \tag{2.32}$$

The normalization constant  $\theta$  is introduced in order to produce stiffness matrices having small condition numbers and can be chosen such that  $\frac{\theta}{D_k(0)} \approx 1$ .

Insertion of these trial function forms into variation equation 2.12a results in a lengthy equation which can be written as follows:

---

<sup>†</sup>Such a choice of  $-G_k^*$  allows the matrix of coefficients to be positive definite. Cf., Chapter 4.

$$\begin{aligned}
& \delta F_1^{*T} \{ b1_1 F_1 + b2_1 G_1 + c1_1 F_2 + c2_1 G_2 \} \\
& \delta G_1^{*T} \{ b3_1 F_1 + b4_1 G_1 + c3_1 F_2 + c4_1 G_2 \} \\
& + \sum_{k=2}^K \delta F_k^{*T} \{ a1_k F_{k-1} + a2_k G_{k-1} + b1_k F_k + b2_k G_k + c1_k F_{k+1} + c2_k G_{k+1} \} \\
& + \sum_{k=2}^K \delta G_k^{*T} \{ a3_k F_{k-1} + a4_k G_{k-1} + b3_k F_k + b4_k G_k + c3_k F_{k+1} + c4_k G_{k+1} \} \\
& \delta F_{K+1}^{*T} \{ a1_{K+1} F_K + a2_{K+1} G_K + b1_{K+1} F_{K+1} + b2_{K+1} G_{K+1} \} \\
& \delta G_{K+1}^{*T} \{ a3_{K+1} F_K + a4_{K+1} G_K + b3_{K+1} F_{K+1} + b4_{K+1} G_{K+1} \} = 0.
\end{aligned} \tag{2.33}$$

where the  $G \times G$  matrix coefficients  $\{a1, \dots, c4\}$  are of the form  $A - \frac{1}{\lambda} B$  and are defined assuming homogeneous regional nuclear constants in section 3 of Appendix B.

The choice of either zero flux,  $F_k = 0$  as well as  $\delta F_k^* = 0$ , or zero current,  $G_k = 0$  as well as  $\delta G_k^* = 0$ , boundary conditions for  $k = 1$  or  $K + 1$  along with arbitrary variations of the remaining  $F_k^*$  and  $G_k^*$  results in a system of  $2K$  equations and  $2K$  unknowns. Figure 2.7 illustrates the matrix form of such a system for the case of zero flux on the left and zero current on the right boundary conditions.

The basis functions and approximation techniques presented in this section are applied to the proposed approximation methods in the next chapter. Also, various techniques for treating zero flux and symmetry boundary conditions are discussed. The matrix properties of the equations resulting from the above finite element approximations and their solution methods are discussed in Chapter 4.

## Chapter 3

DEVELOPMENT OF A CONSISTENT COARSE MESH  
APPROXIMATION METHOD3.1 Formulation

The finite element methods have been shown<sup>32,33</sup> to approximate accurately flux solutions and criticality measurements of multigroup diffusion theory when applied to problems allowing homogeneous nuclear material within the mesh regions. Use of such homogeneous material, while simplifying the calculation of the matrix elements (since numerical integrations are not required), may result in limiting the region mesh sizes allowed unless some type of homogenization procedure is used. If the mesh spacing is chosen such that some or all mesh regions are heterogeneous, then direct application of the variational techniques given in Chapter 2 results in weight averaging the nuclear constants with products of the basis functions and their derivatives, as given by the approximation. Although such a procedure is a direct application of the finite element technique, the accuracy of such methods depends upon the placement of the mesh regions and may vary significantly as their placement is altered.

A more useful homogenization procedure which is commonly used in reactor diffusion theory analysis allows the nuclear material within each mesh region to be homogenized by flux weighting with an assumed flux shape determined *a priori* within that region in order (hopefully) to preserve reaction rates.

In large reactors the core can be thought of as composed of a lattice of heterogeneous fuel subassemblies containing fuel, clad, coolant channels, and/or absorption control rods. Each subassembly can be divided into several distinct homogeneous regions whose few-group microcell macroscopic nuclear constants are found by multi-group energy-dependent calculations.<sup>40</sup> Detailed subassembly solutions,  $\psi_k(r)$ , are then found for each subassembly  $k$  by assuming that the current on the boundary of the subassemblies is zero. Flux weighting the nuclear material in each subassembly with the corresponding detailed subassembly solution for each subassembly region then results in regional homogeneous nuclear constants  $\langle \Sigma_k \rangle$  which may better approximate the physics of the region.

$$\langle \Sigma_k \rangle = \frac{\int_k \psi_k(r) \Sigma_k(r) dr}{\int_k \psi_k(r) dr} \quad (3.1)$$

Proper use of detailed flux weighted constants can lead to accurate criticality measurements, but the detailed *a priori* fine flux structure within each region is lost since it appears only in cross-section homogenization and not in the approximation. Attempts to retain the fine flux structure have only recently been proposed in several multichannel synthesis approximations.<sup>27, 41, 42, 43</sup> Unfortunately, each of these approximations are approximations in themselves and do not reduce to desirable approximations if the detailed flux solutions are themselves constant, as would be the case in large homogeneous regions.

Just as the discontinuous multichannel synthesis approximation method can be shown to reduce to low order difference equations (of the type which could result using the finite element method with constant or flat basis functions) when constant trial functions are used, approximation methods are presented below which retain the given detailed flux structure and also reduce to the higher order finite element approximations. The use of linear or cubic Hermite basis functions in the approximation provides flux continuity and results in better approximation accuracy.

The approximations are presented and discussed for the case of one-dimensional, multigroup diffusion theory. Extension to higher dimensions remains a problem that will require some further study. The approximations which are the linear basis functions are considered in the next section, while the approximations using the cubic Hermite basis functions are considered in section 3.3.

### 3.2 The Proposed Linear Basis Function Approximations

The proposed approximation method utilizing linear basis functions and defined as nonzero within each mesh region  $k$ ,  $k=1$  to  $K$ , is given by the following modal-nodal trial function forms:

$$U_k(z) = \psi_k(x) [ \psi_k^{-1}(0)(1-x)F_k + \psi_k^{-1}(1)x F_{k+1} ] \quad (3.2a)$$

$$U_k^*(z) = \psi_k^*(x) [ \psi_k^{*-1}(0)(1-x)F_k^* + \psi_k^{*-1}(1)x F_{k+1}^* ] \quad (3.2b)$$

$$V_k(z) = \eta_k(x) [ \psi_k^{-1}(0)(1-x)F_k + \psi_k^{-1}(1)x F_{k+1} ] \\ + \frac{1}{h_k} \mathbb{D}_k(x) \psi_k(x) [ \psi_k^{-1}(0)F_k - \psi_k^{-1}(1)F_{k+1} ] \quad (3.2c)$$

$$\begin{aligned}
V_k^*(z) = & \eta_k^*(x) [ \psi_k^{*-1}(0)(1-x)F_k^* + \psi_k^{*-1}(1)x F_{k+1}^* ] \\
& + \frac{1}{h_k} \mathbb{D}_k(x) \psi_k^*(x) [ \psi_k^{*-1}(1) F_{k+1}^* - \psi_k^{*-1}(0) F_k^* ]
\end{aligned} \tag{3.2d}$$

where:

$$x = (z - z_k) / h_k \tag{3.2e}$$

and  $0 \leq x \leq 1$ , as  $z_k \leq z \leq z_{k+1}$ , for each region  $k = 1$  to  $K$ .

$F_k$  is the unknown approximate group flux column vector at node  $z_k$ , and  $\psi_k$ ,  $\psi_k^*$ ,  $\eta_k$ , and  $\eta_k^*$  are  $G \times G$  diagonal matrices composed of the detailed group flux  $\psi_{g,k}(z)$  and group current  $\eta_{g,k}(z)$  solutions, and their adjoints, defined as nonzero only within region  $k$ . Because of the variable transformation between  $z$  and  $x$ ,  $\psi_k(0)$  represents  $\psi_k(z_k)$ , and  $\psi_k(1)$  represents  $\psi_k(z_{k+1})$ ; neither of which, for the moment, is allowed to be zero for any region. The detailed current solutions are given from the detailed flux solutions by Fick's law as

$$\eta_k(z) = -\mathbb{D}_k(z) \frac{d\psi_k(z)}{dz} \tag{3.3a}$$

$$\eta_k^*(z) = +\mathbb{D}_k(z) \frac{d\psi_k^*(z)}{dz} \tag{3.3b}$$

As a result, the current trial functions are related to the flux trial functions by analogous expressions.

Continuity of the flux is imposed by the form of the trial functions since

$$U_k(0) = U_{k-1}(h_{k-1}) = F_k \tag{3.4a}$$

$$U_k^*(0) = U_{k-1}^*(h_{k-1}) = F_k^* \tag{3.4b}$$

The current trial functions, however, are discontinuous. It is evident

by comparison to Eqs. 2.28, that this approximation reduces to the linear basis function finite element method if the detailed flux solutions for each group are taken to be constant.

Insertion of these trial function forms in Eq. 2.12a results in the following variation equation:

$$\begin{aligned}
& \sum_{k=1}^K h_k \int_0^1 \left\{ \psi_k^{*T}(x) \psi_k^{*T^{-1}}(0) (1-x) \delta F_k^{*T} \Lambda_k(x) U_k(x) \right. \\
& + \psi_k^{*T}(x) \psi_k^{*T^{-1}}(1) x \delta F_{k+1}^{*T} \Lambda_k(x) U_k(x) \\
& + \left[ \eta_k^{*T}(x) \psi_k^{*T^{-1}}(0) (1-x) - \frac{1}{h_k} \mathbb{D}_k(x) \psi_k^{*T}(x) \psi_k^{*T^{-1}}(0) \right] \delta F_k^{*T} \mathbb{D}_k^{-1}(x) V_k(x) \\
& \left. + \left[ \eta_k^{*T}(x) \psi_k^{*T^{-1}}(1) x + \frac{1}{h_k} \mathbb{D}_k(x) \psi_k^{*T}(x) \psi_k^{*T^{-1}}(1) \right] \delta F_{k+1}^{*T} \mathbb{D}_k^{-1}(x) V_k(x) \right\} dx = 0
\end{aligned} \tag{3.5}$$

This equation can be written in the form

$$\begin{aligned}
& \delta F_1^{*T} [b_1 F_1 + c_1 F_2] \\
& + \sum_{k=2}^K \delta F_k^{*T} [a_k F_{k-1} + b_k F_k + c_k F_{k+1}] \\
& + \delta F_{K+1}^{*T} [a_{K+1} F_K + b_{K+1} F_{K+1}] = 0
\end{aligned} \tag{3.6}$$

where the  $G \times G$  matrix coefficients  $\{a_k, b_k, c_k\}$  are integral quantities of the form  $A - \frac{1}{\lambda} B$  and are defined in detail in section 1 of Appendix C.

External zero flux boundary conditions are easily imposed by setting  $F_1 = F_{K+1} = 0$ . This requires that  $F_1^*$  and  $F_{K+1}^*$  must then also be zero, which in turn requires the  $\delta F_1^*$  and  $\delta F_{K+1}^*$  coefficients in

Eqs. 3.5 and 3.6 to vanish. Allowing independent variations in the remaining  $F_k^*$ ,  $k = 2$  to  $K$ , results in a matrix problem of the form illustrated in Figure 2.6 which would contain  $K-1$  equations and  $K-1$  unknowns.

Zero current boundary equations are found using symmetry considerations. If, for example, a zero current or symmetry boundary condition is imposed on the right at  $z_{K+1}$ , then a "boundary condition equation" can be derived by assuming a pseudo-region  $k = K + 1$  of width  $h_K$  having mirror image properties of region  $K$  about  $z_{K+1}$  with corresponding symmetric flux and antisymmetric current properties of the detailed flux and current solutions. These properties in pseudo-region  $K+1$  can be related to properties of region  $K$  as a function of  $x$  in each region as

$$D_{K+1}(x) = D_K(1-x) \quad (3.7a)$$

$$\Lambda_{K+1}(x) = \Lambda_K(1-x) \quad (3.7b)$$

and

$$U_{K+1}(x) = U_K(1-x) \quad (3.8a)$$

$$U_{K+1}^*(x) = U_K^*(1-x) \quad (3.8b)$$

$$V_{K+1}(x) = -V_K(1-x) \quad (3.8c)$$

$$V_{K+1}^*(x) = -V_K^*(1-x) \quad (3.8d)$$

The addition of pseudo-region  $K+1$  to the summation in Eq. 3.5 results in the calculation of coefficients  $a_{K+1}$  and  $b_{K+1}$  in Eq. 3.6. Detailed definitions of the  $G \times G$  zero current coefficient matrices  $b_1$ ,  $c_1$ ,  $a_{K+1}$ , and  $b_{K+1}$ , all of which vanish for the case of zero flux boundary conditions, are also given in Appendix C.1. If symmetry is imposed

on both sides of the problem, independent variations in  $F_k^*$  for  $k = 1$  to  $K+1$  result in a matrix problem of  $K+1$  equations and  $K+1$  unknowns of similar form as illustrated in Figure 2.6.

Other boundary conditions may be imposed on the approximation, including albedo and reflector boundary conditions, which specify the flux to current ratio at the boundaries. Such conditions will always lead to a variation equation of the form of Eq. 3.6, where in general the matrix coefficients  $a_2$ ,  $b_2$ ,  $b_K$ , and  $c_K$  as well as the boundary coefficients  $b_1$ ,  $c_1$ ,  $a_{K+1}$ , and  $b_{K+1}$  will have modified definitions.

A serious drawback of the approximation given by Eqs. 3.2 is that it does not allow the use of detailed flux solutions containing explicit zero flux boundary conditions. For this reason the exact solution,  $\psi_k(z) = \Phi_k(z)$  for all  $k$ , is excluded from the class of admissible trial function forms. However, such detailed solutions can be allowed by modifying the trial function forms in the boundary regions. If a detailed solution  $\psi_1(z)$  is given in the first region with the zero flux condition  $\psi_1(z_1) = 0$ , for example, the trial functions of Eqs. 3.2 could be modified for region  $k=1$  as

$$U_1(z) = \psi_1(x) \psi_1^{-1}(1) F_2 \quad (3.9a)$$

$$U_1^*(z) = \psi_1^*(x) \psi_1^{*-1}(1) F_2 \quad (3.9b)$$

$$V_1(z) = \eta_1(x) \psi_1^{-1}(1) F_2 \quad (3.9c)$$

$$V_1^*(z) = \eta_1^*(x) \psi_1^{*-1}(1) F_2^* \quad (3.9d)$$

In this way, the imposed zero flux boundary condition is explicitly given by  $\psi_1(z)$  rather than in the form of the trial function. Similar

trial functions can be given for an explicit zero flux boundary condition in the last region,  $k=K$ .

The use of these special trial functions in the boundary regions alters the definitions of the matrix coefficients  $b_2$  and  $b_K$  as given in Eq. 3.6. Detailed definitions of these coefficients when these special trial functions are used are also included in Appendix C.

Regardless of the types of boundary conditions imposed, Eq. 3.6 results in an  $N \times N$  matrix problem of the form

$$\underline{\mathbf{A}}\underline{\mathbf{F}} = \frac{1}{\lambda} \underline{\mathbf{B}}\underline{\mathbf{F}} \quad (3.10)$$

where  $\underline{\mathbf{A}}$  and  $\underline{\mathbf{B}}$  are independent of  $\lambda$ . The order  $N$  of the matrix equations is dependent upon the chosen boundary conditions, and is given for various choices in Table 3.1.

Table 3.1. Matrix Order  $N$  of the Proposed Linear Basis Function Approximations as a Function of the Imposed Boundary Conditions.

- 1 - Explicit or Implicit Zero Flux
- 2 - Symmetry

Boundary Condition Type		Matrix Order
on Left	on Right	$N$
1	1	$G \times (K-1)$
1	2	$G \times K$
2	1	$G \times K$
2	2	$G \times (K+1)$

### 3.3 The Proposed Cubic Hermite Basis Function Approximation

The proposed modal-nodal approximation method utilizing the cubic Hermite polynomials

$$\begin{aligned}
 p_1(x) &= 1 - 3x^2 + 2x^3 \\
 p_2(x) &= 3x^2 - 2x^3 \\
 p_3(x) &= -x + 2x^2 - x^3 \\
 p_4(x) &= x^2 - x^3
 \end{aligned} \tag{3.11}$$

and their negative derivatives

$$\begin{aligned}
 q_1(x) &= 6x - 6x^2 \\
 q_2(x) &= -6x + 6x^2 \\
 q_3(x) &= 1 - 4x + 3x^2 \\
 q_4(x) &= -2x + 3x^2
 \end{aligned} \tag{3.12}$$

and defined as nonzero only within each mesh region  $k$ , is given by the below regional trial function forms.  $F_k$  and  $G_k$  are again the unknown group column approximate flux and current solutions at  $z_k$  respectively, and the remaining symbols have been previously defined. As in the cubic Hermite finite element method described in section 2.3.4 of Chapter 2,  $\theta$  is an optional normalization parameter.

$$\begin{aligned}
 U_k(z) &= \psi_k(x) [ \psi_k^{-1}(0)p_1(x)F_k + \psi_k^{-1}(1)p_2(x)F_{k+1} \\
 &\quad + h_k \theta \mathbb{D}_k^{-1}(0)\psi_k^{-1}(0)p_3(x)G_k + h_k \theta \mathbb{D}_k^{-1}(1)\psi_k^{-1}(1)p_4(x)G_{k+1} ]
 \end{aligned} \tag{3.13a}$$

$$\begin{aligned}
U_k^*(z) = & \psi_k^*(x) [ \psi_k^{*-1}(0) p_1(x) F_k^* + \psi_k^{*-1}(1) p_2(x) F_{k+1}^* \\
& + h_k \theta \mathbb{D}_k^{-1}(0) \psi_k^{*-1}(0) p_3(x) G_k^* + h_k \theta \mathbb{D}_k^{-1}(1) \psi_k^{*-1}(1) p_4(x) G_{k+1}^* ] \quad (3.13b)
\end{aligned}$$

$$\begin{aligned}
V_k(z) = & \eta_k(x) [ \psi_k^{-1}(0) p_1(x) F_k + \psi_k^{-1}(1) p_2(x) F_{k+1} \\
& + h_k \theta \mathbb{D}_k^{-1}(0) \psi_k^{-1}(0) p_3(x) G_k + h_k \theta \mathbb{D}_k^{-1}(1) \psi_k^{-1}(1) p_4(x) G_{k+1} ] \\
& + \mathbb{D}_k(x) \psi_k(x) [ \frac{1}{h_k} \psi_k^{-1}(0) q_1(x) F_k + \frac{1}{h_k} \psi_k^{-1}(1) q_2(x) F_{k+1} \\
& + \theta \mathbb{D}_k^{-1}(0) \psi_k^{-1}(0) q_3(x) G_k + \theta \mathbb{D}_k^{-1}(1) \psi_k^{-1}(1) q_4(x) G_{k+1} ] \quad (3.13c)
\end{aligned}$$

$$\begin{aligned}
V_k^*(z) = & \eta_k^*(x) [ \psi_k^{*-1}(0) p_1(x) F_k^* + \psi_k^{*-1}(1) p_2(x) F_{k+1}^* \\
& + h_k \theta \mathbb{D}_k^{-1}(0) \psi_k^{*-1}(0) p_3(x) G_k^* + h_k \theta \mathbb{D}_k^{-1}(1) \psi_k^{*-1}(1) p_4(x) G_{k+1}^* ] \\
& - \mathbb{D}_k(x) \psi_k^*(x) [ \frac{1}{h_k} \psi_k^{*-1}(0) q_1(x) F_k^* + \frac{1}{h_k} \psi_k^{*-1}(1) q_2(x) F_{k+1}^* \\
& + \theta \mathbb{D}_k^{-1}(0) \psi_k^{*-1}(0) q_3(x) G_k^* + \theta \mathbb{D}_k^{-1}(1) \psi_k^{*-1}(1) q_4(x) G_{k+1}^* ] \quad (3.13d)
\end{aligned}$$

Again, for the moment,  $\psi_k(0)$  and  $\psi_k(1)$  and their adjoints are not allowed to be zero in any region.

The forms of these trial functions impose both flux and current continuity since:

$$U_k(z_k) = U_{k-1}(z_{k-1} + h_{k-1}) = F_k \quad (3.14a)$$

$$U_k^*(z_k) = U_{k-1}^*(z_{k-1} + h_{k-1}) = F_k^* \quad (3.14b)$$

$$V_k(z_k) = V_{k-1}(z_{k-1} + h_{k-1}) = G_k \quad (3.14c)$$

$$V_k^*(z_k) = V_{k-1}^*(z_{k-1} + h_{k-1}) = -G_k^* \quad (3.14d)$$

where it is assumed that at region mesh points the detailed current solutions are zero:

$$\eta_k(z_k) = \eta_k(z_k + h_k) = 0 \quad (3.15a)$$

$$\eta_k^*(z_k) = \eta_k^*(z_k + h_k) = 0 \quad (3.15b)$$

for all regions  $k = 1$  to  $K$ .

Also, by comparison to Eqs. 2.31, it is evident that this approximation reduces to the cubic Hermite finite element method when the  $\psi_k$ 's are constant, and the  $\eta_k$ 's are correspondingly zero.

The insertion of the above trial function forms into variation equation 2.12a results in a lengthy equation which can be simplified to the following form:

$$\begin{aligned} & \delta F_1^* \left[ b_{11} F_1 + b_{21} G_1 + c_{11} F_2 + c_{21} G_2 \right] \\ & + \delta G_1^* \left[ b_{31} F_1 + b_{41} G_1 + c_{31} F_2 + c_{41} G_2 \right] \\ & + \sum_{k=2}^K \left\{ \delta F_k^* \left[ a_{1k} F_{k-1} + a_{2k} G_{k-1} + b_{1k} F_k + b_{2k} G_k + c_{1k} F_{k+1} + c_{2k} G_{k+1} \right] \right. \\ & \left. + \delta G_k^* \left[ a_{3k} F_{k-1} + a_{4k} G_{k-1} + b_{3k} F_k + b_{4k} G_k + c_{3k} F_{k+1} + c_{4k} G_{k+1} \right] \right\} \\ & + \delta F_{K+1}^* \left[ a_{1K+1} F_K + a_{2K+1} G_K + b_{1K+1} F_{K+1} + b_{2K+1} G_{K+1} \right] \\ & + \delta G_{K+1}^* \left[ a_{3K+1} F_K + a_{4K+1} G_K + b_{3K+1} F_{K+1} + b_{4K+1} G_{K+1} \right] = 0 \end{aligned} \quad (3.16)$$

where the detailed definitions of the twelve integral  $G \times G$  matrix coefficients  $\{a_{1k}, \dots, c_{4k}\}$  of the form  $A - \frac{1}{\lambda} B$  for all  $k$  are given in section 2 of Appendix C.

Boundary conditions for either zero flux or symmetry are easily imposed by setting either  $F_k$  or  $G_k$ , respectively, to zero with  $k=1$  for the conditions on the left at  $z_1$  or  $k=K+1$  for conditions on the right at  $z_{K+1}$ . The corresponding variations for  $k=1$  and  $k=K+1$  then vanish. Allowing arbitrary variations in the remaining  $F_k^*$  and  $G_k^*$  in Eq. 3.16 results in a system of  $2K G \times G$  matrix equations relating  $2K G$  column vector unknowns, as illustrated in Figure 2.7.

Explicit zero flux boundary conditions imposed by  $\psi_1(z_1) = 0$  or  $\psi_K(z_{K+1}) = 0$  can be incorporated into the approximation by modifying the trial function definitions in the boundary regions. The modified flux trial functions in the first region, for example, are

$$\begin{aligned}
 U_1(x) &= \psi_1(x) [\psi_1^{-1}(1)F_{2+h_1} \theta \mathbb{D}_1^{-1}(0) \psi_1^{-1}(0) p_3(x) G_{1+h_1} \theta \mathbb{D}_1^{-1}(1) \psi_1^{-1}(1) p_4(x) G_2] \\
 U_1^*(x) &= \psi_1^*(x) [\psi_1^{*-1}(1)F_{2+h_1}^* \theta \mathbb{D}_1^{-1}(0) \psi_1^{*-1}(0) p_3(x) G_{1+h_1}^* \theta \mathbb{D}_1^{-1}(1) \psi_1^{*-1}(1) p_4(x) G_2^*]
 \end{aligned}
 \tag{3.17}$$

where the current trial functions are again given by Fick's laws. Use of modified trial function forms of this type in the boundary regions results in  $2K$  equations with different definitions of  $c_{3_1}$ ,  $a_{2_2}$ ,  $b_{1_2}$ ,  $b_{2_2}$ , and  $b_{3_2}$  as well as  $b_{1_K}$ ,  $b_{2_K}$ ,  $c_{2_K}$ , and  $a_{3_{K+1}}$ , which are also included in Appendix C.

Other boundary condition restrictions may be imposed on this approximation, but the matrix form of the resulting difference equations will remain unchanged. Only the coefficients defined for  $k=1, 2, K$ , and  $K+1$  will in general be altered.

The matrix equations resulting from this approximation can always be written as

$$\mathbf{A} \underline{\mathbf{F}} = \frac{1}{\lambda} \mathbf{B} \underline{\mathbf{F}} \quad (3.18)$$

where  $\mathbf{A}$  and  $\mathbf{B}$  are  $(G \times 2K)$  by  $(G \times 2K)$  matrices, independent of  $\lambda$ , and  $\underline{\mathbf{F}}$  is the  $G \times K$  column vector of unknowns containing both  $F_k$  and  $G_k$  column vectors for each  $k$ . The matrix properties and solution methods of the matrix equations derived in these proposed approximation methods are discussed in the next chapter.

## Chapter 4

### NUMERICAL SOLUTION TECHNIQUES

The matrix properties of the difference equations resulting from both the proposed approximations and the finite element methods in one dimension, as well as the solution schemes used to solve these equations, are summarized in the following section. Various calculational and programming techniques used in conjunction with these approximation methods and their solution schemes are presented and discussed in section 4.2.

#### 4.1 Solution Methods and Matrix Properties

The matrix equations which result from the approximations given in this report are of the form

$$\underline{A}\underline{F} = \frac{1}{\lambda} \underline{B}\underline{F} \quad (4.1)$$

and are solved using the fission source power iteration method without fission source renormalization.<sup>7,44</sup> The method of solution is illustrated schematically in Figure 4.1. Other definitions of the iteration eigenvalue  $\lambda^{(i)}$  can be found elsewhere.<sup>45</sup>

Figure 4.1 illustrates that an outer iteration solution scheme<sup>46</sup> is used, and that the geometry and nuclear properties of the reactor are not altered. Since the fission source is not normalized by the iteration eigenvalue during the iterations,  $\lambda^{(i)}$  converges to the effective multiplication factor,  $k_{\text{eff}}$ , of the problem. Had fission source renormalization been included, by  $\underline{S}^{(i)} = \underline{B}\underline{F}^{(i)}/\lambda^{(i-1)}$  for example, then  $\lambda^{(i)}$

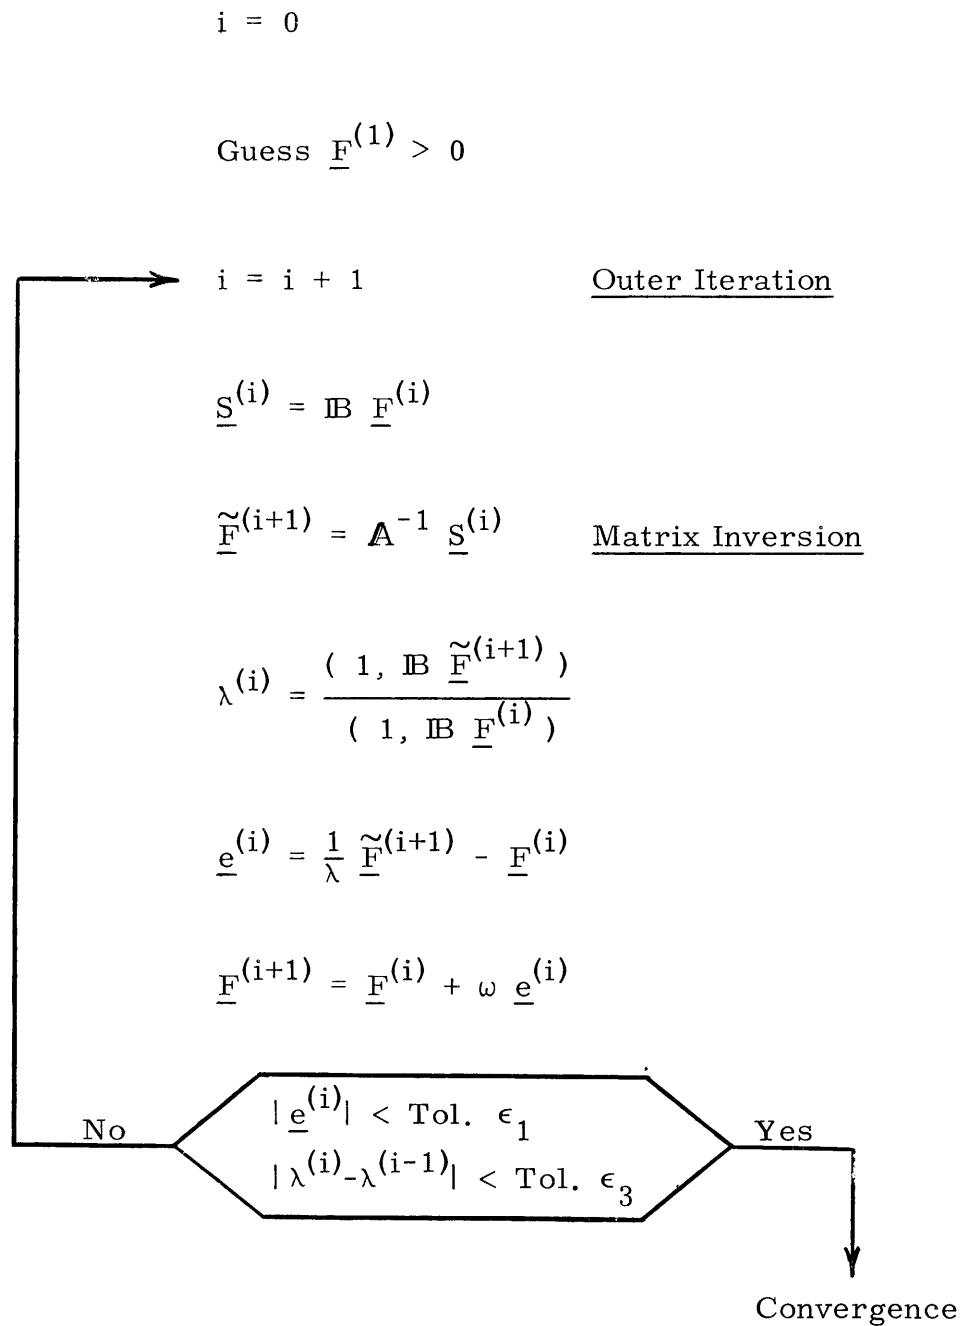

Figure 4.1. Solution of  $\mathbf{A} \underline{F} = \frac{1}{\lambda} \mathbb{B} \underline{F}$  Using the Fission Source Power Iteration Method Without Fission Source Renormalization.

would converge to unity. The  $k_{\text{eff}}$  of the problem would then be simply the product of all of the iteration eigenvalues.<sup>46,47,48</sup>

The matrix inversions required within the iteration scheme were performed directly. Although overrelaxation methods are usually employed only in iterative matrix inversion schemes (or inner iterations),<sup>49</sup> an overrelaxation parameter  $w$ ,  $1 \leq w \leq 2$ , is available in the outer iteration in order to hasten the convergence of the solution vector.

The power method is very appealing to neutron diffusion flux calculations because it converges to the largest or fundamental eigenvalue  $|\lambda_0| > |\lambda_i|$ ,  $i \neq 0$ , and the corresponding eigenvector  $\underline{F}_0$  of the given matrix problem. The convergence rate is governed by the dominance ratio, defined as  $\max_{i \neq 0} |\lambda_i/\lambda_0|$ , in such a way that smaller ratios result in faster convergence. Although the power method will always converge when  $\lambda_0$  is positive and unique, specific matrix properties of  $\mathbf{A}$  and  $\mathbf{B}$  are sufficient but not always necessary to insure convergence to a positive  $k_{\text{eff}}$  and everywhere positive neutron flux approximation.<sup>50</sup>

In many problems the order of  $\mathbf{A}$  may be quite large, and solution methods which require the direct inversion of  $\mathbf{A}$  may not be practical. For the purposes of this report, as in most multigroup calculational schemes, neutron up-scattering will not be permitted. The inversion of  $\mathbf{A}$  is then performed by successive group-iteration techniques.

The equations given in Eq. 4.1 have been defined as ordered first by spatial indexing followed by group indexing within each spatial index. It is convenient to reorder these equations so that they are ordered first by group indexing followed by spatial indexing within each group.

After reordering, Eq. 4.1 can be written as

$$(\mathbb{L} + \mathbb{M}) \underline{F} = \mathbf{T} \underline{F} + \frac{1}{\lambda} \mathbb{B} \underline{F} \quad (4.2a)$$

where

$$\mathbf{A} = \mathbb{L} + \mathbb{M} - \mathbf{T} \quad (4.2b)$$

and:  $\mathbb{L}$ , the stiffness matrix, results from leakage;  $\mathbb{M}$ , the mass matrix, results from absorption;  $\mathbf{T}$  is the group-to-group scattering transfer matrix; and  $\mathbb{B}$  is the fission source production matrix.

Assuming  $K$  spatial unknowns in each of the  $G$  groups,  $\mathbb{L}$  and  $\mathbb{M}$  are  $G \times K$  block diagonal matrices composed of  $G$   $K \times K$  matrices  $\mathbb{L}_g$  and  $\mathbb{M}_g$  of the form

$$\mathbb{L} = \text{Diag}[\mathbb{L}_1, \dots, \mathbb{L}_G] \quad (4.3a)$$

$$\mathbb{M} = \text{Diag}[\mathbb{M}_1, \dots, \mathbb{M}_G] \quad (4.3b)$$

and  $\mathbf{T}$  and  $\mathbb{B}$  are in general full block matrices composed of  $G^2$   $K \times K$  matrices  $\mathbf{T}_{gg'}$  and  $\mathbb{B}_{gg'}$ , respectively. Since only downscattering is permitted,  $\mathbf{T}$  becomes lower block triangular;  $\mathbf{T}_{gg'} = 0$  whenever  $g' \geq g$ . The matrix inversion,  $\underline{\tilde{F}}^{(i+1)} = \mathbf{A}^{-1} \underline{S}^{(i)}$ , can then be solved for the GK unknowns

$$\underline{\tilde{F}}^{(i+1)} = \text{Col} \left[ \underline{\tilde{F}}_1^{(i+1)} \dots \underline{\tilde{F}}_G^{(i+1)} \right] \quad (4.4)$$

by solving successively the following system of group equations:

$$\left[ \begin{array}{l} \text{Do for } g = 1 \text{ to } G: \\ \quad \underline{S}_g^{(i)} = \sum_{g'=1}^G (\mathbf{T}_{gg'} + \mathbb{B}_{gg'}) \underline{F}_{g'}^{(k)} \\ \quad \text{where: } k = \begin{cases} i+1; & g' < g \\ i; & g' \geq g \end{cases} \\ \quad \underline{\tilde{F}}_g^{(i+1)} = (\mathbb{L}_g + \mathbb{M}_g)^{-1} \underline{S}_g^{(i)} \end{array} \right] \quad (4.5)$$

where the updating of the group fission source by the iteration index  $k = i + 1$  for  $g' < g$  generally enables a faster rate of convergence of the outer iteration than  $k = i$ .

The desirable convergence properties of a positive eigenvalue and everywhere positive flux solution when using the above group iteration method depend upon the properties of the  $K \times K$  spatial matrices for each group  $g$ :  $\mathbb{L}_g$ ;  $\mathbb{M}_g$ ; and  $\mathbb{T}_{gg'}$  and  $\mathbb{B}_{gg'}$ , for  $g' = 1$  to  $G$ . Using the Perron-Frohenius theorem,<sup>50</sup> it can be shown that if  $\mathbb{T}_{gg'}$  and  $\mathbb{B}_{gg'}$  are all nonnegative for each group  $g$  and  $\mathbb{L}_g$  and  $\mathbb{M}_g$  are both Stieltjes or S-type matrices<sup>†</sup> for each group  $g$ , then the power method will converge to a positive eigenvalue,  $\lambda_0 > 0$ , and a corresponding positive eigenvector,  $\underline{F}_0 > 0$ . These matrix properties naturally depend upon the form of the spatial approximations employed and generally differ for different approximation schemes.

The conventional finite difference approximation has become popular because the spatial matrices which arise from its use exhibit these desirable properties regardless of the size of the mesh regions chosen. The spatial matrices resulting from the linear finite element method, however, are known to exhibit these properties only if the mesh size is restricted by

$$h_k \leq \max_{g=1 \text{ to } G} \{ \sqrt{6} \ell_{g,k} \} \quad (4.6)$$

where  $\ell_{g,k}$  is the diffusion length,  $\ell_{g,k}^2 = D_{g,k} / \Sigma_{g,k}$ , for group  $g$  in mesh region  $k$ . The spatial matrices resulting from the cubic Hermite

---

<sup>†</sup>A Stieltjes matrix is a real, irreducible, positive definite matrix with nonpositive off-diagonal elements. 7, 50

finite element method do not exhibit these "desirable" characteristics. Since the eigenvector  $\underline{F}$  contains current as well as flux unknowns, convergence to an all-positive solution vector is not desirable.

The properties of the spatial matrices for each group  $g$  resulting from the proposed approximation methods can be found by generalizing the proposed trial function forms in each group as

$$U_g(z) = \sum_{k=1}^K \left[ \underline{P}_{g,k}^{-T}(x) \underline{F}_{g,k} + \underline{P}_{g,k}^{+T} \underline{F}_{g,k+1} \right] \quad (4.7a)$$

$$U_g^*(z) = \sum_{k=1}^K \left[ \underline{P}_{g,k}^{-*T}(x) \underline{F}_{g,k}^* + \underline{P}_{g,k}^{+*T} \underline{F}_{g,k+1}^* \right] \quad (4.7b)$$

where the  $\underline{F}_{g,k}$  are in general column vectors of length  $N$  given by:

$$\underline{F}_{g,k} = F_{g,k} \quad (N = 1) \quad (4.8a)$$

for the linear basis function approximations, and

$$\underline{F}_{g,k} = \text{Col} [ F_{g,k}, G_{g,k} ] \quad (N = 2) \quad (4.8b)$$

for the cubic Hermite basis function approximations. Similar definitions hold for the  $\underline{F}_{g,k}^*$ . The  $\underline{P}_{g,k}^{\pm}(x)$  are column vectors of length  $N$  whose elements are functions of  $z$  (or  $x$ ) defined as nonzero only within region  $k$  which provide the basis for the approximations. The definitions of the  $\underline{P}_{g,k}^{\pm}(x)$  for the proposed approximations are given as follows:

$N = 1$ ; Linear Basis Functions:

$$\underline{P}_{g,k}^{-}(x) = (1-x) \psi_{g,k}^{-1}(0) \psi_{g,k}(x) \quad (4.9a)$$

$$\underline{P}_{g,k}^{+}(x) = x \psi_{g,k}^{-1}(1) \psi_{g,k}(x) \quad (4.9b)$$

$N = 2$ ; Cubic Hermite Basis Functions:

$$\underline{P}_{g,k}^{-}(x) = \text{Col}[p_1(x)\psi_{g,k}^{-1}(0)\psi_{g,k}(x), h_k \theta_{p_3}(x)D_{g,k}^{-1}(0)\psi_{g,k}^{-1}(0)\psi_{g,k}(x)] \quad (4.10a)$$

$$\underline{P}_{g,k}^{+}(x) = \text{Col}[p_2(x)\psi_{g,k}^{-1}(1)\psi_{g,k}(x), h_k \theta_{p_4}(x)D_{g,k}^{-1}(1)\psi_{g,k}^{-1}(1)\psi_{g,k}(x)] \quad (4.10b)$$

where  $\psi_{g,k}(x)$  and  $D_{g,k}(x)$  are the detailed flux solutions and diffusion coefficients of group  $g$ , the polynomials  $p_1(x)$  through  $p_4(x)$  are defined in Eqs. 3.11, and  $0 \leq x \leq 1$  within each region  $k$ . Similar definitions hold for the  $\underline{P}_{g,k}^{\pm*}(x)$ .

Equations 4.7 can be written in matrix form as

$$U_g(z) = \underline{IP}_g(x)\underline{F}_g \quad (4.11a)$$

$$U_g^*(z) = \underline{IP}_g^*(x)\underline{F}_g^* \quad (4.11b)$$

where:

$$\underline{F}_g = \text{Col}(F_{g,1}, \dots, F_{g,K+1}) \quad (4.12a)$$

and  $\underline{IP}_g(x)$  is the  $K$  by  $N(K+1)$  matrix defined by

$$\underline{IP}_g(x) = \begin{bmatrix} \underline{P}_{g,1}^{-T}(x) & \underline{P}_{g,1}^{+T}(x) & & 0 \\ & & & \\ & & & \\ & 0 & & \underline{P}_{g,K}^{-T}(x) & \underline{P}_{g,K}^{+T}(x) \end{bmatrix} \quad (4.12b)$$

$\underline{IP}_g^*(x)$  is defined similarly. Insertion of these trial function forms into variation equation 2.12b for each group  $g$  results in

$$\delta \underline{F}_g^{*T} \int_K \left\{ \dot{\underline{IP}}_g^{*T} \underline{D}_g \dot{\underline{IP}}_g \underline{F}_g + \underline{IP}_g^{*T} \sum_{g'=1}^G \underline{\Lambda}_{gg'} \underline{IP}_{g'} \underline{F}_{g'} \right\} dz = 0 \quad (4.13)$$

where  $\underline{D}_g$  and  $\underline{\Lambda}_{gg'}$  are  $K \times K$  diagonal matrices of the form

$$\underline{D}_g = \underline{D}_g(x) = \text{Diag}[D_{g,1}(x), \dots, D_{g,K}(x)] \quad (4.14a)$$

and

$$\underline{\Lambda}_{gg'} = \underline{\Lambda}_{gg'}(x) = \text{Diag}[\Lambda_{gg',1}(x), \dots, \Lambda_{gg',K}(x)] \quad (4.14b)$$

The quantity  $\dot{\underline{IP}}_g$  represents the derivative of  $\underline{IP}_g(z)$  with respect to  $z$ , and the integration over  $K$  denotes integration over the entire range of  $z$ ;  $z_1 \leq z \leq z_{K+1}$ .

$D_{g,k}$  and  $\Lambda_{gg',k}$ ,

$$\Lambda_{gg',k} = \left( \Sigma_{tg}^{-\Sigma_{gg'}} - \frac{1}{\lambda} \chi_g \nu \Sigma_{fg'} \right)_{\text{in region } k} \quad (4.14c)$$

are the group material constants in mesh region  $k$ , and are usually dependent on  $x$ .  $\underline{\Lambda}_{gg'}$  can thus be conveniently expanded as

$$\underline{\Lambda}_{gg'} = \underline{\Lambda}_g^A - \underline{\Lambda}_{gg'}^S - \frac{1}{\lambda} \underline{\Lambda}_{gg'}^F \quad (4.14d)$$

Allowing arbitrary variations in each element of  $\underline{F}_g^*$  for each group  $g$  in Eq. 4.13 results in the matrix equations

$$(\underline{IL}_g + \underline{IM}_g) \underline{F}_g = \sum_{g'=1}^G \left( \underline{T}_{gg'} + \frac{1}{\lambda} \underline{B}_{gg'} \right) \underline{F}_{g'}; \quad g = 1 \text{ to } G \quad (4.15)$$

as described in Eqs. 4.1 through 4.5, where:

$$\underline{IL}_g = \int_K \dot{\underline{IP}}_g^{*T} \underline{D}_g \dot{\underline{IP}}_g dz \quad (4.16a)$$

$$\underline{IM}_g = \int_K \underline{IP}_g^{*T} \underline{\Lambda}_g^A \underline{IP}_g dz \quad (4.16b)$$

$$\mathbb{T}_{gg'} = \int_K \mathbb{P}_g^{*T} \mathbf{\Lambda}_{gg'}^S \mathbb{P}_{g'} dz \quad (4.16c)$$

$$\mathbb{B}_{gg'} = \int_K \mathbb{P}_g^{*T} \mathbf{\Lambda}_{gg'}^F \mathbb{P}_{g'} dz \quad (4.16d)$$

These matrices are  $N(K+1)$  by  $N(K+1)$  block tridiagonal of similar form whose  $N \times N$  submatrices are integrals of  $N \times N$  dyads. The  $k^{\text{th}}$  row of the product  $\mathbf{\Lambda}_{gg'}^F \mathbb{P}_{g'}$  is, for example:

$$\begin{aligned} [\mathbf{\Lambda}_{gg'}^F \mathbb{P}_{g'}]_k = & \left\{ \int_0^1 h_{k-1} \Lambda_{gg',k-1}(x) \underline{P}_{g,k-1}^{+*}(x) \underline{P}_{g',k-1}^{-T}(x) dx \right\} F_{g',k-1} \\ & + \left\{ \int_0^1 h_{k-1} \Lambda_{gg',k-1}(x) \underline{P}_{g,k-1}^{+*}(x) \underline{P}_{g',k-1}^{+T}(x) dx \right. \\ & \left. + \int_0^1 h_k \Lambda_{gg',k}(x) \underline{P}_{g,k}^{-*}(x) \underline{P}_{g',k}^{-T}(x) dx \right\} F_{g',k} \\ & + \left\{ \int_0^1 h_k \Lambda_{gg',k}(x) \underline{P}_{g,k}^{-*}(x) \underline{P}_{g',k}^{+T}(x) dx \right\} F_{g',k+1} \quad (4.17) \end{aligned}$$

These matrix relationships allow presentation of the following matrix properties.

Theorem 1:  $\mathbb{L}_g$  and  $\mathbb{M}_g$  are guaranteed to be positive definite whenever the detailed weighting functions  $\psi_{g,k}^*(z)$  have a similar shape to that of the detailed flux solutions  $\psi_{g,k}(z)$ , as given by:

$$\psi_{g,k}^*(z) = C_{g,k} \psi_{g,k}(z) \quad (4.18)$$

where  $C_{g,k}$  is a positive constant for each energy group  $g$  and each region  $k$ .

Proof: Under these conditions,  $\underline{P}_{g,k}^{*\pm} = \mathbf{C}_{g,k} \underline{P}_{g,k}^{\pm}$  ;

hence,

$$\mathbb{P}_g^* = \mathbf{C}_g \mathbb{P}_g \quad (4.19a)$$

where

$$\mathbf{C}_g = \text{Diag}(C_{g,1}, \dots, C_{g,K}) \quad (4.19b)$$

First consider  $\mathbb{M}_g$ . Given any arbitrary constant nonzero vector  $\underline{q}$ ,

$$\underline{q}^T \mathbb{M}_g \underline{q} = \int_K (\mathbb{P}_g \underline{q})^T \mathbf{C}_g^T \mathbf{\Lambda}_g^A \mathbb{P}_g \underline{q} \, dz \quad (4.20)$$

and since  $\mathbf{C}_g$  and  $\mathbf{\Lambda}_g^A$  are both positive block diagonal matrices with diagonal submatrices, their product can be factored into

$$\mathbf{C}_g^T \mathbf{\Lambda}_g^A = \left[ (\mathbf{\Lambda}_g^A \mathbf{C}_g)^{\frac{1}{2}} \right]^T (\mathbf{C}_g \mathbf{\Lambda}_g^A)^{\frac{1}{2}} \quad (4.21)$$

Therefore,

$$\underline{q}^T \mathbb{M}_g \underline{q} = \int_K \left[ (\mathbf{C}_g \mathbf{\Lambda}_g^A)^{\frac{1}{2}} \mathbb{P}_g \underline{q} \right]^T \left[ (\mathbf{C}_g \mathbf{\Lambda}_g^A)^{\frac{1}{2}} \mathbb{P}_g \underline{q} \right] \, dz \quad (4.22a)$$

$$= \int_K \mathbb{R}^T \mathbb{R} \, dz \quad (4.22b)$$

which is always greater than zero for arbitrary nonzero  $\underline{q}$ . Hence, by definition,  $\mathbb{M}_g$  is positive definite. A similar proof holds for  $\mathbb{L}_g$  using Eq. 4.16a.

The following corollaries immediately result.

Corollary 1: If Rayleigh-Ritz Galerkin weighting,  $\underline{U}^* = \underline{U}$ , is used in the approximation, then  $\mathbb{L}_g$  and  $\mathbb{M}_g$  are positive definite.

Corollary 2:  $\mathbb{L}_g$  and  $\mathbb{M}_g$  resulting from the finite element methods using linear and cubic Hermite basis functions are both positive definite.

Corollary 3: If  $\mathbb{L}_g$  and  $\mathbb{M}_g$  are positive definite, then so is the matrix  $(\mathbb{L}_g + \mathbb{M}_g)$ . These three matrices are then also symmetric.

It is also interesting to note the properties of  $\mathbb{L}_g$  and  $\mathbb{M}_g$  for cases of symmetry; that is, when the material properties and detailed flux solutions are symmetric about the center of each coarse mesh region  $k$ . Such symmetry occurs in regular repeating reactor geometries, and is denoted by:

$$D_{g,k}(x) = D_{g,k}(1-x) \quad (4.23a)$$

and

$$\Lambda_{g,k}(x) = \Lambda_{g,k}(1-x) \quad (4.23b)$$

Hence,

$$\psi_{g,k}(x) = \psi_{g,k}(1-x) \quad (4.23c)$$

and

$$\eta_{g,k}(x) = -\eta_{g,k}(1-x) \quad (4.23d)$$

and similarly for the weighting fluxes and currents. Under such conditions, the  $\underline{P}_{g,k}^+(x)$  and  $\underline{P}_{g,k}^-(x)$  support functions can be found by inspection of Eqs. 4.9 and 4.10 to obey the following symmetries:

For  $N = 1$ :

$$\underline{P}_{g,k}^\mp(x) = \underline{P}_{g,k}^\pm(1-x) \quad (4.24a)$$

$$\dot{\underline{P}}_{g,k}^\mp(x) = -\dot{\underline{P}}_{g,k}^\pm(1-x) \quad (4.24b)$$

For  $N = 2$ :

$$\underline{P}_{g,k}^{\mp}(x) = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \underline{P}_{g,k}^{\pm}(1-x) \quad (4.24c)$$

$$\dot{\underline{P}}_{g,k}^{\mp}(x) = - \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \dot{\underline{P}}_{g,k}^{\pm}(1-x) \quad (4.24d)$$

where the following symmetries of the polynomials defined in Eqs. 3.11 have been used:

$$\begin{aligned} p_1(x) &= p_2(1-x) \\ p_3(x) &= -p_4(1-x) \\ q_1(x) &= -q_2(1-x) \\ q_3(x) &= q_4(1-x) \end{aligned} \quad (4.25)$$

Similar identities with identical signs hold for the weighting quantities  $\underline{P}_{g,k}^{\pm*}(x)$ .

Theorem 2: For cases of symmetry, as given above, the matrices  $\mathbb{L}_g$ ,  $\mathbb{M}_g$ ,  $\mathbb{T}_{gg'}$ , and  $\mathbb{B}_{gg'}$  are all symmetric regardless of the relation of  $\psi_{g,k}^*(x)$  to  $\psi_{g,k}(x)$ .

Proof: Referring to Eq. 4.17,  $\mathbb{L}_g$ , for example, is symmetric only if

$$\int_0^1 h_k D_{g,k}(x) \dot{\underline{P}}_{g,k}^{+*}(x) \dot{\underline{P}}_{g,k}^{-T}(x) dx = \int_0^1 h_k D_{g,k}(x) \dot{\underline{P}}_{g,k}^{-*}(x) \dot{\underline{P}}_{g,k}^{+T}(x) dx \quad (4.26)$$

This can be shown for any  $N$  by changing variables in one of the integrals from  $x$  to  $1-x'$  and using the symmetry properties of Eqs. 4.23 and 4.24. Similar proofs hold for the other matrices.

It is unfortunate that the above symmetry conditions do not allow direct proof that  $\mathbb{L}_g$  and  $\mathbb{M}_g$  have positive diagonal elements and are also diagonally dominant (for at least one row) for arbitrary positive and symmetric detailed flux solutions. Under such conditions,  $\mathbb{L}_g$  and  $\mathbb{M}_g$  would then be positive definite, since they are block tridiagonal with nonzero diagonal elements and hence irreducible. Instead, these conditions can be used to obtain a set of algebraic equations which, for completely arbitrary detailed flux solutions, must be satisfied in order that  $\mathbb{L}_g$  and  $\mathbb{M}_g$  be positive definite.

The requirement that  $\mathbb{L}_g$  and  $\mathbb{M}_g$  be positive definite is useful only in the inversion of  $(\mathbb{L}_g + \mathbb{M}_g)$ . Although the inversion can always be performed using Gaussian elimination techniques, the property of positive definiteness allows the use of Cholesky's method, discussed in the next section, which is faster and requires less computer storage.

#### 4.2 Calculational and Programming Techniques

Calculation of the one-dimensional subassembly detailed fluxes, currents, and adjoint solutions, as well as detailed "exact" or reference solutions, were performed using the program REF2G described in section 1 of Appendix D. Assuming subassembly  $k$  to be divided into  $N$  homogeneous intervals at nodes  $t_i$  and of width  $hs_i$ , the program uses fine mesh linear finite element approximations to calculate the detailed flux solutions for each group. Omitting group subscripts, the detailed flux solution for each group in subassembly  $k$  is represented by a set of  $N+1$  points

$$\psi_k(x) = \{\psi_{k,i} : i = 1, N+1\} \quad (4.27)$$

where  $\psi_k(x)$  is linear between points. Detailed group current solutions  $\eta_k(x)$  are represented by a set of N points

$$\eta_k(x) = \{ \eta_{k,i} : i = 1, N \} \quad (4.28)$$

which are found from the converged flux solutions by Fick's law

$$\eta_{k,i} = \frac{1}{hs_i} D_{k,i} [ \psi_{k,i} - \psi_{k,i+1} ]; \quad i = 1, N \quad (4.29)$$

where  $D_{k,i}$  is the diffusion constant homogeneous in interval  $i$ .  $\eta_k(x)$  is of constant value,  $\eta_{k,i}$ , within each interval. The forms of these solutions are illustrated in Figure 4.2.

In order to approximate the symmetry boundary conditions imposed on the detailed subassembly flux solutions, small intervals  $hs_1$  and  $hs_N$  are defined at the edges of each subassembly. The detailed current solutions can then be made to have zero boundary values by setting  $\eta_{k,1}$  and  $\eta_{k,N}$  to zero. However, since the currents in each interval are defined as inversely proportional to the mesh size, the calculated boundary currents using this scheme may not be small enough to be negligible.

Explicit zero current boundary conditions can be imposed on the detailed current solutions by transforming the above discontinuous current  $\eta_k(x)$  into a continuous current solution  $\tilde{\eta}_k(x)$  represented by a set of N+1 points

$$\tilde{\eta}_k(x) = \{ \tilde{\eta}_{k,i} : i = 1 \text{ to } N+1 \} \quad (4.30)$$

where  $\tilde{\eta}_k(x)$  is linear between points, as also illustrated in Figure 4.2. By seeking to minimize the mean square error between  $\eta_k(x)$  and  $\tilde{\eta}_k(x)$  within each interval  $i$ , variational techniques yield the following set of N-1 equations for each group:

$$x = \frac{1}{h_k} (z - z_k)$$

$0 \leq x \leq 1$ ; for each subassembly  $k$ ;  $k = 1$  to  $K$ .

$$y = \frac{1}{hs_i} (t - t_i)$$

$0 \leq y \leq 1$ ; for each interval  $i$  in subassembly  $k$ ;  $i = 1$  to  $N$ .

Figure 4.2. Subassembly Notations and Detailed Solutions

$$\begin{aligned}
& \left(\frac{1}{6} h s_{i-1}\right) \tilde{\eta}_{k,i-1} + \frac{1}{3} \left(h s_{i-1} + h s_i\right) \tilde{\eta}_{k,i} + \left(\frac{1}{6} h s_i\right) \tilde{\eta}_{k,i+1} \\
& = \left(\frac{1}{2} h s_{i-1}\right) \eta_{k,i-1} + \left(\frac{1}{2} h s_i\right) \eta_{k,i} ; \quad i = 2 \text{ to } N \quad (4.31)
\end{aligned}$$

These equations, given the  $\eta_{k,i}$  from Eq. 4.29, are easily solved for the  $\tilde{\eta}_{k,i}$ ,  $i = 2$  to  $N$ , where  $\tilde{\eta}_{k,1}$  and  $\tilde{\eta}_{k,N+1}$  are set to zero. Both forms of the detailed currents,  $\eta_k(x)$  and  $\tilde{\eta}_k(x)$ , are allowed for use in the proposed approximation methods.

The proposed methods using linear and cubic Hermite basis functions have been programmed into computer codes LINEAR and CUBIC which are described respectively in sections 2 and 3 of Appendix D.

The matrix elements required for use in the approximation methods are integrals of products of subassembly detailed solutions and polynomial functions. These integrals are calculated, for each index  $k$ , from the basic integral unit

$$\text{BIU}_k = \int_0^1 f_k(x) g_k(x) C_k(x) x^n h_k dx \quad (4.32)$$

where the functions  $f_k(x)$  and  $g_k(x)$  represent flux and/or current solutions for same or different groups. These functions may be either constant within each interval

$$f_k(x) = \{f_{k,i} : i = 1 \text{ to } N\} \quad (4.33)$$

or of linear form within each interval

$$f_k(x) = \{(1-y)f_{k,i} + yf_{k,i+1} : i = 1 \text{ to } N\} \quad (4.34)$$

where  $y = \frac{1}{h s_i} (t - t_i)$ , as defined in Figure 4.2.  $C_k(x)$  represents a

group nuclear constant which is homogeneous in each interval

$$C_k(x) = \{C_{k,i} : i = 1 \text{ to } N\} \quad (4.35)$$

and  $n$  is a positive integer exponent in the range  $0 \leq n \leq 6$ . Since the following remarks concern only subassembly  $k$ , the index  $k$  is dropped for simplicity.

The basic integral unit can be broken into integrals over each interval by transforming variables from  $x$  to  $y$ . The result

$$\text{BIU}_k = \frac{1}{h_k^n} \sum_{i=1}^N h s_i \int_0^1 f_i(y) g_i(y) C_i(t_i + h s_i y)^n dy \quad (4.36)$$

can be integrated analytically by expanding  $(t_i + h s_i y)^n$  into a binomial series. The results of these integrations for any  $n$  depend only on the given forms of  $f(x)$  and  $g(x)$ , and are summarized in Table 4.1.

The coarse mesh flux-weighting homogenization calculations were performed using the above basic integral unit with  $n = 0$ . In these calculations a linear form of  $f(x)$ , representing the detailed subassembly flux solutions from REF2G, and a constant value of  $g(x) = 1$  were used.

Once the elements of the matrices of the approximation methods have been formed, considerable computer storage can be saved by collapsing the sparse band-structured matrices into full matrix form using row index transformations. In this way, a  $N \times N$  tridiagonal matrix  $\mathbb{L}$  resulting from the use of linear basis functions can be stored as the  $N \times 3$  matrix  $\mathbb{L}'$  by

$$(\mathbb{L}')_{ik} = (\mathbb{L})_{ij} \quad (4.37)$$

where  $k = j + 2 - i$ , and  $k$  values outside  $1 \leq k \leq 3$  are omitted.

Table. 4.1. Calculation of the Basic Integral Unit in Subassembly k.

1. Constant  $f(x)$  and constant  $g(x)$  in each interval i:

$$\text{BIU}_k = \frac{1}{h_k^n} \sum_{i=1}^N \left\{ \text{hs}_i f_i g_i C_i \sum_{\ell=0}^n b_\ell^n t_i^{n-\ell} \text{hs}_i^\ell \frac{1}{(\ell+1)} \right\}$$

2. Linear  $f(x)$  and constant  $g(x)$  in each interval i:

$$\text{BIU}_k = \frac{1}{h_k^n} \sum_{i=1}^N \left\{ \text{hs}_i g_i C_i \sum_{\ell=0}^n b_\ell^n t_i^{n-\ell} \text{hs}_i^\ell \left[ \frac{f_i}{(\ell+1)(\ell+2)} + \frac{f_{i+1}}{(\ell+2)} \right] \right\}$$

3. Linear  $f(x)$  and linear  $g(x)$  in each interval i:

$$\text{BIU}_k = \frac{1}{h_k^n} \sum_{i=1}^N \left\{ \text{hs}_i C_i \sum_{\ell=0}^n b_\ell^n t_i^{n-\ell} \text{hs}_i^\ell \left[ \frac{2f_i g_i}{(\ell+1)(\ell+2)(\ell+3)} + \frac{f_i g_{i+1} + f_{i+1} g_i}{(\ell+2)(\ell+3)} + \frac{f_{i+1} g_{i+1}}{(\ell+3)} \right] \right\}$$

where

$$b_\ell^n = \frac{n!}{\ell! (n-\ell)!}$$

is the binomial series coefficient.

Similarly, a  $N \times N$  matrix  $\mathbb{L}$  of half-band width equal to three, which results from the use of cubic Hermite basis functions, can be stored as the  $N \times 6$  matrix  $\mathbb{L}'$ , as given above, where in this case:

$$k = j - i + 3 + \begin{cases} 1 & \text{for } i \text{ odd} \\ 0 & \text{for } i \text{ even} \end{cases} \quad (4.38)$$

and  $k$  values outside  $1 \leq k \leq 6$  are omitted.

In those cases where the mass and stiffness matrices are both positive definite, Cholesky's method of matrix factorization,

$$\mathbb{L} = \mathbb{G} \mathbb{G}^T \quad (4.39)$$

where  $\mathbb{L}$  is positive definite and  $\mathbb{G}$  is lower triangular, can be used to solve the matrix inversion for each group in the power method. The matrix elements  $g_{ij} = (\mathbb{G})_{ij}$  are calculated from the elements  $l_{ij} = (\mathbb{L})_{ij}$  by the following algorithm: <sup>51</sup>

$$\left. \begin{array}{l} \text{For each } j = 1 \text{ to } N: \\ \quad g_{jj} = \left[ l_{jj} - \sum_{k=1}^{j-1} g_{jk}^2 \right]^{\frac{1}{2}} \\ \quad \text{For each } i = j+1 \text{ to } N: \\ \quad \quad g_{ij} = \left[ l_{ij} - \sum_{k=1}^{j-1} g_{ik} g_{jk} \right] / g_{jj} \end{array} \right\} \quad (4.40)$$

Similar algorithms of a more complex form are used in the computer codes in conjunction with the matrix collapsing schemes given above.

## Chapter 5

## NUMERICAL RESULTS

5.1 Nuclear Constants and Subassembly Geometry

The effectiveness and accuracy of the proposed approximation methods were examined using one-dimensional, one- and two-group reactor configurations composed of representative PWR fuel subassemblies. Four separate subassemblies with identical geometry but different number constants are considered. Each subassembly is represented as an 18-cm, homogeneous fuel region of low, medium, or high enrichment, surrounding a 1-cm centrally located absorption rod or water channel. Two-group regional nuclear constants used to represent such PWR subassembly geometries are given in Table 5.1,<sup>52</sup> where all fission neutrons are assumed to be born in the fast group. These constants were collapsed into representative one-group constants using the standard infinite medium group reduction procedure for two groups:

$$\langle \Sigma \rangle_{1G} = \frac{1}{(1+\alpha)} (\Sigma_1 + \alpha \Sigma_2) \quad (5.1)$$

where  $\Sigma_1$  and  $\Sigma_2$  are macroscopic cross sections for the fast and thermal groups, respectively, and  $\alpha$  is the infinite medium thermal to fast flux ratio.<sup>53</sup> The resulting one-group regional constants for the fuel and rod regions are given in Table 5.2, where the flux ratios of the three fuel regions have been averaged in order to collapse the absorption rod constants.

Table 5.1. Representative Two-Group, 18-cm, PWR  
Subassembly Regional Nuclear Constants.  
 $\chi_1 = 1.0$ ;  $\chi_2 = 0.0$ .

Region Material	$\Sigma_T$	$\nu\Sigma_f$	D	$\Sigma_{21}$
Fuel A: Low w/o	.0259	.00485	1.396	.0179
	.0532	.0636	.388	
Fuel B: Medium w/o	.0260	.00553	1.397	.0172
	.0710	.102	.389	
Fuel C: High w/o	.0261	.00659	1.399	.0168
	.0832	.129	.387	
Absorption Rod	.0452	0.0	1.0	0.0
	.959	0.0	1.0	
Water	.0383	0.0	1.63	.0380
	.0108	0.0	.275	

Fast group constants appear first for each region material, followed by thermal group constants. Fission neutrons are assumed to be born in the fast group only.

Table 5.2. Representative One-Group, 18-cm, PWR  
Subassembly Regional Nuclear Constants.

Region Material	$\Sigma_T$	$\nu\Sigma_f$	D
Fuel A: Low w/o	.0329	.0199	1.14
Fuel B: Medium w/o	.0348	.0244	1.20
Fuel C: High w/o	.0357	.0272	1.23
Absorption Rod	.235	0.0	1.0
Water	.0136	0.0	.414

Four subassembly configurations, labeled A through D, were used in the one- and two-group test configurations, and are illustrated in Figure 5.1. Subassemblies labeled A, B, and C contain homogeneous fuel of low, medium, and high enrichment, respectively, surrounding the 1-cm absorption rod while subassembly D contains low enriched homogeneous fuel surrounding a 1-cm water channel.

## 5.2 Subassembly Detailed Solutions and Homogenized Nuclear Constants

The detailed flux and current solutions for each subassembly were found using the computer code REF2G with symmetry boundary conditions and a 68-mesh region per subassembly geometry as indicated in Figure 5.2. The resulting one-group detailed flux solutions for each subassembly are shown in Figure 5.3. The resulting two-group detailed flux and adjoint flux solutions for each subassembly are shown in Figures 5.4 and 5.5, respectively.

Homogeneous subassembly group constants for use in the finite element approximations were found by flux weighting the group cross sections in each subassembly by the corresponding subassembly detailed group flux solutions. The resulting homogenized one-group constants for each subassembly are given in Table 5.3, and the resulting homogenized two-group constants are given in Table 5.4. The results of homogenizing the diffusion coefficient as the transport cross section,  $1/\langle 1/D \rangle$ , as well as by direct homogenization,  $\langle D \rangle$ , are included in the tables. The results of both schemes were found to differ at most by only 2%. The directly homogenized diffusion coefficients,  $\langle D \rangle$ , were used in the finite element approximations.

Fast group constants appear first for each subassembly, followed by thermal group constants.

Before applying the proposed approximation methods to complex reactor geometries, test runs were performed in order to evaluate the differences between using either flux or adjoint flux weighting, and using current solutions of either constant or linear form in each subassembly interval, as described in section 4.2. The test problem consisted of three consecutive Type A subassemblies with symmetry boundary conditions imposed on each end so that the converged eigenvalue  $\lambda$  ( $k_{\text{eff}}$ ) should be identical to that of the detailed flux solution of subassembly A. Entire subassemblies were chosen as the mesh regions so that the proposed synthesis methods should converge to flux values of unity, and current values of zero. The numerical results of these tests for the one- and two-group cases are summarized in Table 5.5. Although the choice of weighting function did not influence the results for either approximation, use of current solutions of the linear form enables better eigenvalue accuracy. In addition, the results when using currents of linear form converged to flux values of unity and current values of zero, as expected, while results using the constant current form produced errors of about 0.5 % in the converged flux and 0.01 % in the converged current at interior points. Although the difference in accuracy between the use of these different current forms is small, the small flux and current errors resulting from the use of the constant current form may lead to larger errors in larger and more complex problems. For the above reasons, the linear current form was used in the following case studies. Adjoint weighting was also used. Although the use of adjoint weighting has not been shown to guarantee the success of Cholesky's method in the numerical solution scheme, no difficulties with its use were ever encountered.

Table 5.5. Test Results Using Three Consecutive Type A Subassemblies.

### 5.3 Case Studies and Results

Four one-dimensional reactor configurations, each made up of different combinations of types of subassemblies, are considered in the case studies below. One-group calculations were performed only for the first case, and two-group calculations were performed in all cases. Entire 18-cm subassemblies were used as coarse mesh regions in each case, while the effect of using half-subassembly mesh regions was also included in Case 1. The geometry and subassembly configurations of the case studies are shown in Figure 5.6.

Three separate approximation methods were used to calculate converged detailed flux solutions for comparison in each case. They are:

1. The proposed approximation methods using heterogeneous nuclear constants and subassembly detailed flux solutions for coarse mesh solutions.
2. The finite element methods using subassembly homogenized nuclear constants for coarse mesh solutions.
3. The linear finite element method for fine mesh reference solutions.

Calculations of both the proposed approximation and the coarse mesh finite element method using linear basis functions were performed using program LINEAR, while the corresponding cubic Hermite basis function approximations were performed using program CUBIC. The fine mesh reference solutions were calculated using program REF2G, and the results of these approximations were compared and analyzed by program ANALYZE. Descriptions of these programs are given in Appendix D.

Case 1 :

Case 2 :

Case 3 :

Case 4 :

Figure 5.6. Geometry of the Four Case Studies Composed of Types of Subassemblies

The results of each case study are divided into the two approximation method categories as defined below.

1. The linear basis function approximation
  - A. Linear FEM;
 

(The linear finite element method using homogenized coarse mesh nuclear constants)
  - B. Linear Synth;
 

(The proposed approximation method using heterogeneous coarse mesh nuclear constants and detailed coarse mesh solutions)
2. The cubic Hermite basis function approximations
  - A. Cubic FEM
  - B. Cubic Synth

The results of the approximations in each category are compared to the reference solution by examining:

1. The converged eigenvalues  $\lambda$  ( $k_{\text{eff}}$ ) and their percent normalized eigenvalue error,
 
$$\% \lambda = (\lambda_{\text{Ref}} - \lambda_{\text{Conv}}) / \lambda_{\text{Ref}} \times 100\%$$
2. Composite graphs of the converged detailed group flux solutions  $U_g(z)$  normalized to equivalent power levels
3. The fractional normalized power levels  $P(k)$  calculated for each 18-cm subassembly  $k$  by

$$P(k) = \frac{\int_{\text{Sub. } k} \sum_{g=1}^G \nu \Sigma_{fg}(z) U_g(z) dz}{\int_{\text{All Subs.}} \sum_{g=1}^G \nu \Sigma_{fg}(z) U_g(z) dz} \quad (5.2)$$

and their percent normalized errors

$$\%P(k) = (P(k)_{\text{Ref}} - P(k)_{\text{Conv}}) / P(k)_{\text{Ref}} \times 100\% \quad (5.3)$$

5.3.1. Case 1: Three different subassemblies of Types A, B, and C with symmetry boundary conditions.

The graphical results of the one-group approximation methods for this case are shown in Figures 5.7 and 5.8, while the results of the two-group approximation methods are presented in Figures 5.9 - 5.12. Only the coarse mesh boundaries are labeled in the figures, which indicates that entire 18-cm subassemblies were used as the coarse mesh regions. Two-group results using only half-subassemblies as the coarse mesh regions are shown in Figures 5.13 - 5.16. The reference solutions were calculated using 150-mesh regions, as defined by the symmetric partitioning

$$5(1 \text{ cm}) + 4(.5 \text{ cm}) + 4(.25 \text{ cm}) + 4(.125 \text{ cm}) + 8(.0625 \text{ cm})$$

in each of the three subassemblies. The converged approximation eigenvalues and fractional normalized subassembly power levels for the one- and two-group calculations are summarized in Table 5.6. The fractional powers,  $P(k)$ , for each subassembly are listed in the reference solution column, while the percent errors,  $\%P(k)$  are listed in the approximation columns.

It is apparent from these results that the proposed approximation methods, and in particular the method utilizing the cubic Hermite basis functions, approximate to a high degree of accuracy the detailed reference spatial flux. Comparison of the eigenvalue and fractional power results in Table 5.6 indicates that comparable if not superior measurements are obtained using the proposed methods in this case.

It is interesting to note the effects of employing the given subassembly heterogeneous nuclear constants rather than subassembly homogenized nuclear constants for use in the finite element method calculations. Under such conditions, the finite element method becomes identical to the proposed methods in which the heterogeneous nuclear constants and constant or flat subassembly solutions are used. Two-group calculations using the cubic Hermite approximation method were performed for Case 1 and are presented in Figures 5.17 and 5.18. This scheme was found to give very poor detailed flux results, converge to an eigenvalue 21% in error, and yield an average of 20% error in the fractional normalized power levels in each subassembly. This example clearly illustrates the necessity for the use of homogenized constants in the finite element method, or equivalently, the importance of the subassembly detailed solutions in the proposed approximations.

5.3.2. Case 2: Three different subassemblies of Types D, B, and C with symmetric boundary conditions.

The results of the two-group approximations for Case 2 are presented in Figures 5.19 - 5.22, where entire subassemblies were taken as the coarse mesh regions. The reference solutions were calculated using the same reference mesh geometry as in Case 1. The converged eigenvalues and fractional normalized power levels in each subassembly are summarized in Table 5.7. These results better illustrate the superiority of the cubic Hermite basis function approximations over the linear basis function approximations, and the superiority of the proposed approximations over the finite element method in all aspects.

5.3.3. Case 3: Half-core reflected PWR composed of an 18-cm water reflector, the seven subassemblies C,C,C,A,A,A,D, and half of subassembly D. Zero flux boundary conditions are imposed outside the reflector, and symmetry is imposed in the center of the last D-type subassembly.

The Case 3 results of the two-group approximations using full 18-cm coarse mesh regions in all but the last 9-cm region are presented in Figures 5.23 - 5.26, and summarized in Table 5.8. The reference solutions were obtained using 198 mesh regions given by the symmetric partitioning

$$2(2 \text{ cm}) + 2(1 \text{ cm}) + 4(.5 \text{ cm}) + 2(.25 \text{ cm}) + 2(.25 \text{ cm})$$

in each of the subassemblies, and 18 (1 cm) regions in the reflector.

The use of many subassemblies containing absorption rods throughout the reactor, except in the center subassemblies where water channels are present, results in central peaked fluxes with large gradients and, by comparison, a relatively small thermal neutron peak in the reflector.

Both coarse mesh methods were found to overestimate the flux in the subassemblies near the reflector, and underestimate the flux in the central subassembly regions regardless of the type of basis function approximations used. The larger inaccuracies of the linear basis function methods can be in part attributed to the fact that these methods cannot approximate the peaked thermal flux in the reflector, and result in large flux values in the subassemblies nearest the reflector. The cubic Hermite basis function approximations, however, are better able to approximate both the thermal flux reflector peak and the complex

neutron leakage across the core, and give better results. Table 5.8 indicates that the cubic Hermite basis function approximations better approximate the detailed reference solutions, and that results obtained using the cubic Hermite finite element method were for this case better than those obtained using either of the proposed approximations. The ability of these methods to approximate large thermal flux peaks in the reflector regions is considered in the next case.

5.3.4. Case 4: Half-core reflected PWR composed of an 18-cm water reflector, the seven subassemblies D,D,D,C,D,D,A, and half of subassembly Type A. Zero flux boundary conditions are imposed in the center of the last Type A subassembly.

The Case 4 geometry produces a large but detailed thermal flux in the half-core region and a large thermal peak in the reflector region, as seen from the results in Figures 5.27 - 5.30. The reference solutions were calculated using the reference mesh geometry as given in Case 3. The results of the approximations are summarized in Table 5.9.

The results show that the linear basis function approximations cannot approximate accurately the thermal flux reflector peak and result in large flux and fractional power errors in the subassemblies near the reflector. The cubic Hermite basis function approximations, on the other hand, are better able to approximate this thermal peak and result in much more accurate power levels, especially in the first subassembly region.

The Case 4 results typify the approximation accuracy of both the finite element method and the proposed approximation method. In general, the cubic Hermite basis function approximations are superior to the linear basis function approximations, and the proposed methods give comparable or superior results as compared to those obtained from the finite element method using the same class of basis functions. In this case, the proposed method using cubic Hermite basis functions was able to estimate the reference eigenvalue within 0.04%, closely approximate the detailed reference flux solution to within a few percent at all spatial points, and result in fractional normalized power levels in each subassembly with less than 5% error.

## Chapter 6

## CONCLUSIONS AND RECOMMENDATIONS

6.1. Characteristics of the Proposed Approximation Methods

The use of detailed subassembly flux solutions or other a priori flux shapes directly in the spatial shape or trial function form of flux approximations in reactor physics has resulted in many coarse mesh approximation schemes which are classified in the broad area of overlapping multichannel synthesis. The proposed approximation methods are similar to existing synthesis methods of this kind, but are unique in that they reduce to conventional and well understood approximation methods in regions where little or no spatial flux information is given, or in completely homogeneous regions. In contrast, the overlapping synthesis methods proposed to date do not. This characteristic is especially important in calculations involving homogeneous regions, of which reflector regions are a prime example.

The proposed approximations are very similar to coarse mesh finite element method approximations in which detailed flux behavior has been used to flux-weight the nuclear constants in each region. The methods are conceptually different and become equivalent only when all of the coarse mesh regions are homogeneous.

The matrix equations resulting from the use of the proposed methods are identical in form to those resulting from the finite element method utilizing similar basis functions. In addition, the matrix

elements of the proposed methods are curiously different from those of the finite element methods using detailed flux-weighted nuclear constants. Although the spatial mass and stiffness matrices of the proposed methods for each group have been proven to be positive definite only for the case of Galerkin flux weighting, the use of adjoint weighting in all of the cases considered did not alter these properties. In addition, the proposed methods were found always to converge to a positive eigenvalue and to flux shapes which were everywhere positive.

The numerical results indicate that the proposed methods are able to predict accurate criticality or  $k_{\text{eff}}$  measurements and regional power levels as well as to approximate the reference detailed flux shapes for each group with a high degree of accuracy. The results indicate that in general, use of the proposed methods results in superior criticality estimates over those obtained by the use of the finite element method with flux-weighted constants; this behavior was observed for each type of basis function approximation. Moreover, each of the proposed methods is in general vastly superior to its finite element method counterparts in approximating the actual detailed flux behavior and regional as well as total power levels.

Detailed flux behavior could be reintroduced into the results of the homogenized finite element methods by normalizing the detailed subassembly solutions in each coarse mesh region to match the power levels of the converged results in each region. The detailed solutions resulting from such a procedure would be discontinuous at the region boundaries and may, to some extent, exhibit the fine flux structure present in the results of the proposed methods. However, the results

are not expected to be as good as an approximation as those of the proposed methods, since the current coupling or diffusion approximation is not made until after the coarse mesh homogenization procedure.

## 6.2 Applicability and Limitations

Because the matrix forms of the equations which result from the use of the proposed methods are identical to those which result from the use of the finite element methods, the proposed approximations can be incorporated into existing finite element approximation schemes. Although additional integrations must be performed in the proposed methods, they can be reduced to sums of known products so that little additional computation time is required.

As in any coarse mesh approximation method, inaccurate results can occur when the coarse mesh region sizes chosen are too large. For a given region size, the accuracy of the results for any approximation scheme is unknown. The accuracy of the finite element methods is known to improve geometrically as the mesh size is decreased, resulting in a useful error criterion for the method. A disadvantage of the proposed methods is that no such error criterion has been developed. The inability to predict error estimates has always been a major drawback of synthesis techniques. However, the use of such methods, and use of the proposed methods, has been shown to be justified through proper physical insight and experience.

### 6.3. Recommendations for Future Work

Obviously the next step is the application of these proposed methods to two-dimensional diffusion problems. However, the one-dimensional problem still contains areas which may deserve closer attention. One such area is the examination of the matrix properties of both the finite element method and the proposed approximation methods which are necessary in order to guarantee convergence to a positive eigenvalue and an everywhere positive flux solution. Another area is the development of error criteria for the proposed methods. The close similarity between the proposed methods and the finite element methods may allow an extension or generalization of characteristics which hitherto have belonged only to the finite element methods.

The usefulness of the proposed methods depends on their applicability and accuracy in two- and three-dimensional diffusion problems. Just as the finite element approximations can be derived in two- or three-dimensions using variational modal-nodal techniques, so can the proposed methods for multidimensional problems. The proposed trial functions could be defined as continuous at mesh nodes, but may in general be discontinuous along mesh line interfaces. In order that the flux and current trial functions not be allowed to be discontinuous at identical spatial points, the current trial functions would then have to be defined as continuous across these interfaces. The use of the proposed class of trial function forms in the two-dimensional problem will raise the challenge of extending the spatial overlapping synthesis methods of this type to multidimensional reactor problems.

## BIOGRAPHICAL NOTE

The author is a native Californian. Born in San Francisco August 19, 1945, he was raised in Orange, and upon graduation from Orange High School in 1963, he received the Bank of America Award in Mathematics and the Orange County Industrial Education Association Award in Electronics.

He then attended the University of California at Berkeley, and supported by special as well as Regents' Scholarship awards, graduated in 1967 from the School of Engineering with a Bachelor of Science degree in Physics. He was elected to Tau Beta Pi, Phi Beta Kappa, and received a four-year letter in varsity gymnastics.

The author then enrolled at the Massachusetts Institute of Technology. Supported by an Atomic Energy Commission Special Fellowship in Nuclear Engineering, he received the Master of Science degree from the Department of Nuclear Engineering in 1969.

As a research associate in the Space-Time Kinetics Project in the same department, the author completed this work and obtained the degree of Doctor of Philosophy in 1972.

While at M. I. T. the author was active in many organizations, most notable of which was the M. I. T. Rugby Football Club.

APPENDICES

## Appendix A

## TABLE OF SYMBOLS

$g$	Energy group index which runs from the highest to the lowest energy group as $g = 1$ to $G$ .
$\phi_g(r)$	Scalar neutron flux in energy group $g$ (neutrons/cm <sup>2</sup> · sec).
$\underline{J}_g(r)$	Vector neutron current in energy group $g$ (neutrons/cm <sup>2</sup> · sec).
$D_g(r)$	Diffusion coefficient for neutrons in energy group $g$ (cm).
$\Sigma_g(r)$	Macroscopic total removal cross section in energy group $g$ (cm <sup>-1</sup> ).
$\nu\Sigma_{fg}(r)$	Macroscopic fission-production cross section in energy group $g$ (cm <sup>-1</sup> ).
$\Sigma_{gg'}(r)$	Macroscopic transfer cross section from energy group $g'$ to energy group $g$ (cm <sup>-1</sup> ).
$\chi_g$	Fission spectrum yield in energy group $g$ .
$\lambda$	The eigenvalue or criticality of the diffusion problem.
$\Phi(r), \Phi^*(r)$	Scalar group flux column vector of length $G$ and its adjoint.
$\underline{J}(r), \underline{J}^*(r)$	Vector group current column vector of length $G$ and its adjoint.

$\Lambda(r)$	$G \times G$ group material removal, scattering, and production matrix.
$D(r)$	$G \times G$ diagonal group diffusion coefficient matrix.
$U(r), U^*(r)$	Scalar group flux and weighting flux trial function column vectors of length $G$ .
$\underline{V}(r), \underline{V}^*(r)$	Vector group current and weighting current trial function column vectors of length $G$ .
$k$	One-dimensional spatial index which runs from the leftmost first region to the rightmost $K$ -th region, as $k = 1$ to $K$ .
$z$	The one-dimensional axis variable divided into $K$ regions such that each region $k$ is bounded by nodes $z_k$ and $z_{k+1}$ .
$x$	A dimensionless variable defined in each region $k$ as $x = (z - z_k)/(z_{k+1} - z_k)$ , such that $0 \leq x \leq 1$ as $z_k \leq z \leq z_{k+1}$ .
$F_k$	Approximate one-dimensional group flux solution at node $z_k$ .
$G_k$	Approximate one-dimensional group current solution at node $z_k$ .
$\psi_k(z), \psi_k^*(z)$	Detailed one-dimensional subassembly flux and weighting flux solutions in coarse mesh region $k$ whose form is linear within each homogeneous subassembly interval.
$\eta_k(z), \eta_k^*(z)$	Detailed one-dimensional subassembly current and weighting current solutions in coarse mesh region $k$ whose form is <u>constant</u> within each homogeneous subassembly interval.

$\tilde{\eta}_k(z), \tilde{\eta}_k^*(z)$	Detailed one-dimensional subassembly current and weighting current solutions in coarse mesh region k whose form is <u>linear</u> within each homogeneous subassembly interval.
<u>A</u>	Discretized matrix form of the G×G group diffusion, absorption, and scattering matrices.
<u>B</u>	Discretized matrix form of the G×G group fission-production matrix.
<u>F</u>	The unknown approximate group flux solution vector which may contain group current unknowns.
% λ	Normalized eigenvalue percent error: $\% \lambda = (\lambda_{\text{Reference}} - \lambda_{\text{Method}}) / \lambda_{\text{Reference}} \times 100\%.$
P(k)	Fractional power produced in coarse mesh region k when the total power produced has been normalized to unity.
% P(k)	Normalized fractional power percent error: $\% P(k) = [P(k)_{\text{Reference}} - P(k)_{\text{Method}}] / P(k)_{\text{Reference}} \times 100\%.$

## Appendix B

DIFFERENCE EQUATION COEFFICIENTS RESULTING FROM  
USE OF THE FINITE ELEMENT  
APPROXIMATION METHODS

The  $G \times G$  matrix coefficients resulting from the conventional finite difference approximation, the linear finite element approximation, and the cubic Hermite finite element approximation in one-dimensional multigroup diffusion theory are defined below in sections B.1, B.2, and B.3, respectively. The coefficients are given in terms of assumed homogeneous regional nuclear constants through the use of the  $G \times G$  group matrices  $\mathbb{D}_k$  and  $\mathbf{\Lambda}_k$ , where  $\mathbf{\Lambda}_k = \mathbb{M}_k - \mathbf{\Gamma}_k - \frac{1}{\lambda} \mathbb{B}_k$ , which are defined in Chapter 2 and are constant for each region  $k$ , where  $k = 1$  to  $K$ .

More general definitions of these coefficients may be found from the coefficients resulting from the use of the proposed approximations, given in Appendix C, by requiring that  $\psi_k(z)$  be constant and  $\eta_k(z)$  be zero in each region  $k$ .

B.1. Coefficients of the Conventional Finite Difference Equations  
(as defined by Eqs. 2.16)

Interior Coefficients;  $k = 2$  to  $K$ :

$$a_k = -\mathbb{D}_{k-1}/h_{k-1}$$

$$b_k = \frac{1}{2}(\mathbf{\Lambda}_{k-1}h_{k-1} + \mathbf{\Lambda}_k h_k) + \mathbb{D}_{k-1}/h_{k-1} + \mathbb{D}_k/h_k$$

$$c_k = -\mathbb{D}_k/h_k$$

Symmetry Boundary Condition Coefficients:

$$b_1 = \frac{1}{2} \mathbf{\Lambda}_1 h_1 + \mathbb{D}_1 / h_1$$

$$c_1 = -\mathbb{D}_1 / h_1$$

$$a_{K+1} = -\mathbb{D}_K / h_K$$

$$b_{K+1} = \frac{1}{2} \mathbf{\Lambda}_K h_K + \mathbb{D}_K / h_K$$

B. 2. Coefficients of the Linear Finite Element Method Equations  
(as defined by Eqs. 2.30)

Interior Coefficients;  $k = 2$  to  $K$ :

$$a_k = \frac{1}{6} \mathbf{\Lambda}_{k-1} h_{k-1} - \mathbb{D}_{k-1} / h_{k-1}$$

$$b_k = \frac{1}{3} [\mathbf{\Lambda}_{k-1} h_{k-1} + \mathbf{\Lambda}_k h_k] + \mathbb{D}_{k-1} / h_{k-1} + \mathbb{D}_k / h_k$$

$$c_k = \frac{1}{6} \mathbf{\Lambda}_k h_k - \mathbb{D}_k / h_k$$

Symmetry Boundary Condition Coefficients:

$$b_1 = \frac{1}{3} \mathbf{\Lambda}_1 h_1 + \mathbb{D}_1 / h_1$$

$$c_1 = \frac{1}{6} \mathbf{\Lambda}_1 h_1 - \mathbb{D}_1 / h_1$$

$$a_{K+1} = \frac{1}{6} \mathbf{\Lambda}_K h_K - \mathbb{D}_K / h_K$$

$$b_{K+1} = \frac{1}{3} \mathbf{\Lambda}_K h_K + \mathbb{D}_K / h_K$$

B.3. Coefficients of the Cubic Hermite Finite Element Method Equations (as defined by Eq. 2.33)

Interior Coefficients;  $k=2$  to  $K$ :

$$a1_k = \frac{9}{70} \Lambda_{k-1} h_{k-1} - \frac{6}{5} \mathbb{D}_{k-1} / h_{k-1}$$

$$a2_k = \left( -\frac{13}{420} \Lambda_{k-1} h_{k-1}^2 \mathbb{D}_{k-1}^{-1} + \frac{1}{10} \right) \theta$$

$$b1_k = \frac{13}{35} \left( \Lambda_{k-1} h_{k-1} + \Lambda_k h_k \right) + \frac{6}{5} \left( \mathbb{D}_{k-1} / h_{k-1} + \mathbb{D}_k / h_k \right)$$

$$b2_k = \frac{11}{210} \left( \Lambda_{k-1} h_{k-1}^2 \mathbb{D}_{k-1}^{-1} - \Lambda_k h_k^2 \mathbb{D}_k^{-1} \right) \theta$$

$$c1_k = \frac{9}{70} \Lambda_k h_k - \frac{6}{5} \mathbb{D}_k / h_k$$

$$c2_k = \left( \frac{13}{420} \Lambda_k h_k^2 \mathbb{D}_k^{-1} - \frac{1}{10} \right) \theta$$

$$a3_k = \left( \frac{13}{420} \mathbb{D}_{k-1}^{-1} h_{k-1}^2 \Lambda_{k-1} - \frac{1}{10} \right) \theta$$

$$a4_k = \left( -\frac{1}{140} \mathbb{D}_{k-1}^{-1} h_{k-1}^3 \Lambda_{k-1} \mathbb{D}_{k-1}^{-1} - \frac{1}{30} h_{k-1} \mathbb{D}_{k-1}^{-1} \right) \theta^2$$

$$b3_k = \frac{11}{210} \left( \mathbb{D}_{k-1}^{-1} h_{k-1}^2 \Lambda_{k-1} - \mathbb{D}_k^{-1} h_k^2 \Lambda_k \right) \theta$$

$$b4_k = \left[ \frac{1}{105} \left( \mathbb{D}_{k-1}^{-1} h_{k-1}^3 \Lambda_{k-1} \mathbb{D}_{k-1}^{-1} + \mathbb{D}_k^{-1} h_k^3 \Lambda_k \mathbb{D}_k^{-1} \right) + \frac{2}{15} \left( h_{k-1} \mathbb{D}_{k-1}^{-1} + h_k \mathbb{D}_k^{-1} \right) \right] \theta^2$$

$$c3_k = \left( -\frac{13}{420} \mathbb{D}_k^{-1} h_k^2 \Lambda_k + \frac{1}{10} \right) \theta$$

$$c4_k = \left( -\frac{1}{140} \mathbb{D}_k^{-1} h_k^3 \Lambda_k \mathbb{D}_k^{-1} - \frac{1}{30} h_k \mathbb{D}_k^{-1} \right) \theta^2$$

Zero Flux Boundary Condition Coefficients:

$$b_{4_1} = \left( \frac{1}{105} \mathbb{D}_1^{-1} h_1^3 \mathbf{\Lambda}_1 \mathbb{D}_1^{-1} + \frac{2}{15} h_1 \mathbb{D}_1^{-1} \right) \theta^2$$

$$c_{3_1} = \left( -\frac{13}{420} \mathbb{D}_1^{-1} h_1^2 \mathbf{\Lambda}_1 + \frac{1}{10} \right) \theta$$

$$c_{4_1} = \left( -\frac{1}{140} \mathbb{D}_1^{-1} h_1^3 \mathbf{\Lambda}_1 \mathbb{D}_1^{-1} - \frac{1}{30} h_1 \mathbb{D}_1^{-1} \right) \theta^2$$

$$a_{3_{K+1}} = \left( \frac{13}{420} \mathbb{D}_K^{-1} h_K^2 \mathbf{\Lambda}_K - \frac{1}{10} \right) \theta$$

$$a_{4_{K+1}} = \left( -\frac{1}{140} \mathbb{D}_K^{-1} h_K^3 \mathbf{\Lambda}_K \mathbb{D}_K^{-1} - \frac{1}{30} h_K \mathbb{D}_K^{-1} \right) \theta^2$$

$$b_{4_{K+1}} = \left( \frac{1}{105} \mathbb{D}_K^{-1} h_K^3 \mathbf{\Lambda}_K \mathbb{D}_K^{-1} + \frac{2}{15} h_K \mathbb{D}_K^{-1} \right) \theta^2$$

Symmetry Boundary Condition Coefficients:

$$b_{1_1} = \frac{13}{35} \mathbf{\Lambda}_1 h_1 + \frac{6}{5} \mathbb{D}_1 / h_1$$

$$c_{1_1} = \frac{9}{70} \mathbf{\Lambda}_1 h_1 - \frac{6}{5} \mathbb{D}_1 / h_1$$

$$c_{2_1} = \left( \frac{13}{420} \mathbf{\Lambda}_1 h_1^2 \mathbb{D}_1^{-1} - \frac{1}{10} \right) \theta$$

$$a_{1_{K+1}} = \frac{9}{70} \mathbf{\Lambda}_K h_K - \frac{6}{5} \mathbb{D}_K / h_K$$

$$a_{2_{K+1}} = \left( -\frac{13}{420} \mathbf{\Lambda}_K h_K^2 \mathbb{D}_K^{-1} + \frac{1}{10} \right) \theta$$

$$b_{1_{K+1}} = \frac{13}{35} \mathbf{\Lambda}_K h_K + \frac{6}{5} \mathbb{D}_K / h_K$$

## Appendix C

DIFFERENCE EQUATION COEFFICIENTS RESULTING FROM  
USE OF THE PROPOSED APPROXIMATION METHODS

The  $G \times G$  matrix coefficients resulting from the proposed approximation methods using (1) linear basis functions, and (2) cubic Hermite basis functions, in one-dimensional multigroup diffusion theory are defined below in sections C.1 and C.2, respectively.

The coefficients are given as integrands of functions of  $x$  where the integration of every coefficient-integrand over a region

$$\text{Coefficient} = \int_0^1 [\text{Coefficient-Integrand}(x)] dx$$

is understood.

In order to simplify the forms of the coefficient-integrands, it is convenient to define the following  $G \times G$  matrices:

$$\mathbb{K}_k(x) = \psi_k^{*T}(x) \mathbb{A}_k(x) h_k \psi_k(x)$$

$$\mathbb{L}_k(x) = \eta_k^{*T}(x) \mathbb{D}_k^{-1}(x) h_k \eta_k(x)$$

$$\mathbb{P}_k(x) = \psi_k^{*T}(x) \eta_k(x)$$

$$\mathbb{Q}_k(x) = \eta_k^{*T}(x) \psi_k(x)$$

$$\mathbb{R}_k(x) = \frac{1}{h_k} \psi_k^{*T}(x) \mathbb{D}_k(x) \psi_k(x)$$

for each region  $k$ . In each approximation below, two sets of polynomial functions  $p_1(x) \dots p_{2N}(x)$  and  $q_1(x) \dots q_{2N}(x)$  are given

which represent the basis functions of the approximation and their negative derivatives, where  $N = 1$  for the linear basis function approximations and  $N = 2$  for the cubic Hermite basis function approximations.

The  $G \times G$  coefficient-integrands are then listed in terms of these matrices and polynomials by the  $G \times G$  collapsed matrices  $\mathbb{E}_k^{i,j}(x)$  defined as

$$\begin{aligned} \mathbb{E}_k^{i,j}(x) = & p_i(x)p_j(x)\mathbb{K}_k(x) - p_i(x)p_j(x)\mathbb{L}_k(x) + q_i(x)p_j(x)\mathbb{P}_k(x) \\ & - p_i(x)q_j(x)\mathbb{Q}_k(x) + q_i(x)q_j(x)\mathbb{R}_k(x) \end{aligned}$$

for given values of  $i$  and  $j$  for each region  $k$ , where  $k = 1$  to  $K$ . It should be noted that  $\mathbb{E}_k^{i,j}(x)$  is not symmetric about  $i$  and  $j$ ; i. e.:

$$\mathbb{E}_k^{i,j}(x) \neq \mathbb{E}_k^{j,i}(x), \quad \text{for } i \neq j.$$

### C.1. Coefficient-Integrands of the Proposed Approximation Method Equations Using Linear Basis Functions (as defined by Eq. 3.6)

These coefficients are given in terms of the polynomial functions

$$p_1(x) = (1-x)$$

$$p_2(x) = x$$

$$q_1(x) = 1$$

$$q_2(x) = -1$$

for use in the  $\mathbb{E}_k^{i,j}(x)$  below.

Interior Coefficient-Integrands;  $k = 2$  to  $K$ :

$$a_k(x) = \psi_{k-1}^{*\text{T}(1)} \mathbb{E}_{k-1}^{2,1}(x) \psi_{k-1}^{-1}(0)$$

$$b_k(x) = \psi_{k-1}^{*\text{T}(1)} \mathbb{E}_{k-1}^{2,2}(x) \psi_{k-1}^{-1}(1) + \psi_k^{*\text{T}(0)} \mathbb{E}_k^{1,1}(x) \psi_k^{-1}(0)$$

$$c_k(x) = \psi_k^{*\text{T}(0)} \mathbb{E}_k^{1,2}(x) \psi_k^{-1}(1)$$

Symmetry Coefficient-Integrands:

$$b_1(x) = \psi_1^{*\text{T}(0)} \mathbb{E}_1^{1,1}(x) \psi_1^{-1}(0)$$

$$c_1(x) = c_k(x); \text{ where } k = 1$$

$$a_{K+1}(x) = a_k(x); \text{ where } k = K + 1$$

$$b_{K+1}(x) = \psi_K^{*\text{T}(1)} \mathbb{E}_K^{2,2}(x) \psi_K^{-1}(1)$$

Implied Zero Flux Boundary Condition Coefficient-Integrands

(Corresponding with the modified trial functions of the type in Eqs. 3.9)

$$b_2(x) = \psi_1^{*\text{T}(1)} [\mathbb{K}_1(x) - \mathbb{L}_1(x)] \psi_1^{-1}(1) + \psi_2^{*\text{T}(0)} \mathbb{E}_2^{1,1}(x) \psi_2^{-1}(0)$$

$$b_K(x) = \psi_{K-1}^{*\text{T}(1)} \mathbb{E}_{K-1}^{2,2}(x) \psi_{K-1}^{-1}(1) + \psi_K^{*\text{T}(0)} [\mathbb{K}_K - \mathbb{L}_K] \psi_K^{-1}(0)$$

C.2. Coefficient-Integrands of the Proposed Approximation Method  
Equations Using Cubic Hermite Basis Functions (as defined  
in Eq. 3.16)

These coefficients are given in terms of the polynomials  $p_1(x)$  through  $p_4(x)$  and  $q_1(x)$  through  $q_4(x)$ , previously defined in Eqs. 3.11 and 3.12, for use in the  $\mathbb{I}_k^{i,j}(x)$  below.

Interior Coefficient-Integrands;  $k = 2$  to  $K$ :

$$a1_k(x) = \psi_{k-1}^{*-T(1)} \mathbb{I}_{k-1}^{2,1}(x) \psi_{k-1}^{-1}(0)$$

$$a2_k(x) = \psi_{k-1}^{*-T(1)} \mathbb{I}_{k-1}^{2,3}(x) \psi_{k-1}^{-1}(0) \mathbb{D}_{k-1}^{-1}(0) \theta$$

$$b1_k(x) = \psi_{k-1}^{*-T(1)} \mathbb{I}_{k-1}^{2,2}(x) \psi_{k-1}^{-1}(1) + \psi_k^{*-T(0)} \mathbb{I}_k^{1,1}(x) \psi_k^{-1}(0)$$

$$b2_k(x) = \psi_{k-1}^{*-T(1)} \mathbb{I}_{k-1}^{2,4}(x) \psi_{k-1}^{-1}(1) \mathbb{D}_{k-1}^{-1}(1) \theta \\ + \psi_k^{*-T(0)} \mathbb{I}_k^{1,3}(x) \psi_k^{-1}(0) \mathbb{D}_k^{-1}(0) \theta$$

$$c1_k(x) = \psi_k^{*-T(0)} \mathbb{I}_k^{1,2}(x) \psi_k^{-1}(1)$$

$$c2_k(x) = \psi_k^{*-T(0)} \mathbb{I}_k^{1,4}(x) \psi_k^{-1}(1) \mathbb{D}_k^{-1}(1) \theta$$

$$a3_k(x) = \psi_{k-1}^{*-T(1)} \mathbb{D}_{k-1}^{-1}(1) \mathbb{I}_{k-1}^{4,1}(x) \psi_{k-1}^{-1}(0) \theta$$

$$a4_k(x) = \psi_{k-1}^{*-T(1)} \mathbb{D}_{k-1}^{-1}(1) \mathbb{I}_{k-1}^{4,3}(x) \psi_{k-1}^{-1}(0) \mathbb{D}_{k-1}^{-1}(0) \theta^2$$

$$\begin{aligned}
b3_k(x) &= \psi_{k-1}^{*\text{T}(1)} \mathbb{D}_{k-1}^{-1}(1) \mathbb{E}_{k-1}^{4,2}(x) \psi_{k-1}^{-1}(1) \theta \\
&\quad + \psi_k^{*\text{T}(0)} \mathbb{D}_k^{-1}(0) \mathbb{E}_k^{3,1}(x) \psi_k^{-1}(0) \theta \\
b4_k(x) &= \psi_{k-1}^{*\text{T}(1)} \mathbb{D}_{k-1}^{-1}(1) \mathbb{E}_{k-1}^{4,4}(x) \psi_{k-1}^{-1}(1) \mathbb{D}_{k-1}^{-1}(1) \theta^2 \\
&\quad + \psi_k^{*\text{T}(0)} \mathbb{D}_k^{-1}(0) \mathbb{E}_k^{3,3}(x) \psi_k^{-1}(0) \mathbb{D}_k^{-1}(0) \theta^2 \\
c3_k(x) &= \psi_k^{*\text{T}(0)} \mathbb{D}_k^{-1}(0) \mathbb{E}_k^{3,2}(x) \psi_k^{-1}(1) \theta \\
c4_k(x) &= \psi_k^{*\text{T}(0)} \mathbb{D}_k^{-1}(0) \mathbb{E}_k^{3,4}(x) \psi_k^{-1}(1) \mathbb{D}_k^{-1}(1) \theta^2
\end{aligned}$$

Zero Flux Boundary Condition Coefficient-Integrands:

$$\begin{aligned}
b4_1(x) &= \psi_1^{*\text{T}(0)} \mathbb{D}_1^{-1}(0) \mathbb{E}_1^{3,3}(x) \psi_1^{-1}(0) \mathbb{D}_1^{-1}(0) \theta^2 \\
c3_1(x) &= c3_k(x); \text{ where } k = 1 \\
c4_1(x) &= c4_k(x); \text{ where } k = 1 \\
a3_{K+1}(x) &= a3_k(x); \text{ where } k = K+1 \\
a4_{K+1}(x) &= a4_{K+1}(x); \text{ where } k = K+1 \\
b4_{K+1}(x) &= \psi_K^{*\text{T}(1)} \mathbb{D}_K^{-1}(1) \mathbb{E}_K^{4,4}(x) \psi_K^{-1}(1) \mathbb{D}_K^{-1}(1) \theta^2
\end{aligned}$$

Symmetry Boundary Condition Coefficient-Integrands:

$$b1_1(x) = \psi_1^{*T}{}^{-1}(0) \mathbb{E}_1^{1,1}(x) \psi_1^{-1}(0)$$

$$c1_1(x) = c1_k(x); \text{ where } k = 1$$

$$c2_1(x) = c2_k(x); \text{ where } k = 1$$

$$a1_{K+1}(x) = a1_k(x); \text{ where } k = K+1$$

$$a2_{K+1}(x) = a2_k(x); \text{ where } k = K+1$$

$$b1_{K+1}(x) = \psi_K^{*T}{}^{-1}(1) \mathbb{E}_K^{2,2}(x) \psi_K^{-1}(1)$$

Implied Zero Flux Boundary Condition Coefficient-Integrands  
(corresponding with the modified trial functions of the type in  
Eq. 3.17):

$$\left. \begin{aligned} c3_1(x) &= c3_k(x); \text{ where } k=1 \\ a2_2(x) &= a2_k(x); \text{ where } k=2 \\ b1_2(x) &= b1_k(x); \text{ where } k=2 \\ b2_2(x) &= b2_k(x); \text{ where } k=2 \\ b3_2(x) &= b3_k(x); \text{ where } k=2 \end{aligned} \right\} \text{ and where } \begin{cases} p_1(x) = 0 \\ p_2(x) = 1 \\ q_1(x) = 0 \\ q_2(x) = 0 \end{cases}$$

$$\left. \begin{aligned} b1_K(x) &= b1_k(x); \text{ where } k=K \\ b2_K(x) &= b2_k(x); \text{ where } k=K \\ c2_K(x) &= c2_k(x); \text{ where } k=K \\ b3_K(x) &= b3_k(x); \text{ where } k=K \\ a3_{K+1}(x) &= a3_k(x); \text{ where } k=K+1 \end{aligned} \right\} \text{ and where } \begin{cases} p_1(x) = 1 \\ p_2(x) = 0 \\ q_1(x) = 0 \\ q_2(x) = 0 \end{cases}$$

## Appendix D

## DESCRIPTION OF THE COMPUTER PROGRAMS

The computer programs REF2G, LINEAR, CUBIC, and ANALYZE are described respectively in the following four sections. The programs are written in FORTRAN IV, allow double precision calculations, and were used with the I.B.M. 360/65 and 370/155 FORTRAN G compilers at the M.I.T. Information Processing Center. Sample storage requirements and execution times of the programs are summarized in Table D.1.

The power method employed in the first three programs allows a maximum of 300 iterations to converge, and program execution continues after this limit. Initial group flux shapes are sinusoidal or flat, depending upon the boundary conditions chosen.

The input and output data of each program are divided into data blocks for ease of representation as described below.

#### D.1. Description of Program REF2G

REF2G finds the reference solutions of the one-dimensional, two-group diffusion equations of each case study, or the detailed subassembly solutions of each subassembly, using the linear finite element approximation method. The program allows up to a total of two hundred homogeneous fine mesh regions and employs combinations of both zero flux and symmetry boundary conditions. Identical material regions can be automatically repeated with no additional input.

Table D.1. Sample Storage Requirements and Execution Times of the Programs for Two-Group Results. Obtained using the M.I.T. I.B.M. 360/155.

Storage Requirements in Bytes (without overlays):

REF2G:	260 K
LINEAR:	200 K
CUBIC:	250 K
ANALYZE:	205 K

C.P.U. Execution Times in Minutes:

REF2G:	Detailed Subassembly Solutions (68 regions) <sup>a</sup> :	.120	
	Case 1 Reference Solution (150 regions) <sup>b</sup> :	.238	
	Case 4 Reference Solution (198 regions) <sup>b</sup> :	.644	
LINEAR:	Case 1 Synthesis (Homogenized <sup>c</sup> ) Method (3 regions):	.284	(.157)
	Case 4 Synthesis (Homogenized <sup>c</sup> ) Method (9 regions):	.296	(.209)
CUBIC:	Case 1 Synthesis (Homogenized <sup>c</sup> ) Method (3 regions):	1.227	(.183)
	Case 4 Synthesis (Homogenized <sup>c</sup> ) Method (9 regions):	1.464	(.328)
ANALYZE:	Case 1 Linear (Cubic Hermite) Basis Functions:	.087	(.108)
	Case 4 Linear (Cubic Hermite) Basis Functions:	.122	(.139)

---

a. Including adjoint flux and current calculations.

b. Not including adjoint calculations.

c. Including .126 minutes for calculation of the two-group homogenized constants.

Options for plotting graphically the history of the converging spatial flux as well as the converging eigenvalue are also available. In addition, the program allows the calculation of the adjoint flux and current solutions.

The approximate current solutions are linear within each mesh region and are calculated from the converged flux solutions using Eqs. 4.29 and 4.31. The converged flux and current solutions and the converged adjoint solutions can be punched out for future use as described below.

#### A. Reference Solution Input Block

Card Type 1: Format (20A4)

An Appropriate Problem Title

Card Type 2: Format (2I5, 3E10.3, 5I5)

KR Total number of homogeneous fine mesh regions.  
 $KR \leq 200$ .

IBC Boundary Condition Option

1. Zero flux on both boundaries
2. Zero flux on the left, symmetry on the right
3. Symmetry on the left, zero flux on the right
4. Symmetry on both boundaries

EPS1 Iteration tolerance to be met by differences between elements of successive iteration solution vectors:

$$|F_j^{(i)} - F_j^{(i-1)}| < \epsilon_1; \text{ for all } j$$

EPS2 Iteration tolerance to be met by the mean square error between successive iteration solution vectors:

$$\left\{ \sum_j [F_j^{(i)} - F_j^{(i-1)}]^2 \right\}^{\frac{1}{2}} < \epsilon_2$$

- EPS3 Iteration tolerance to be met by the difference between successive iteration eigenvalues:
- $$|\lambda^{(i)} - \lambda^{(i-1)}| < \epsilon_3$$
- IPLOT Allows printed graphical display of the converging flux solution:
- 0 No display
  - 1 Plot only the resultant normalized flux
  - 2 Plot a normalized history of the converging flux
- JPLOT Allows printed graphical display of the history of the converging eigenvalue when JPLOT = 1.
- IPUNCH Allows punched output when IPUNCH = 1.
- ISEE Allows printing of storage information:
- 0 No information printed
  - 1 Input regional properties are printed
  - 2 Input regional properties as well as the Common/B5/ storage arrays and the Common/B3/ power method matrices are printed.
- NOADJ Adjoint calculations are performed when NOADJ = 0, and bypassed if NOADJ = 1.

Card Type 3: Format (25I2)

- ITF(k) The consecutive type-number of each region from left to right as  $k = 1$  to KR. Allows for repeating identical regions with no additional input.

Card Type 3 is repeated KR/25 times (rounded off to the next highest integer).

Card Type 4: Format (2F10.5)

- CHI(1), CHI(2) The fission yields  $\chi_1$  and  $\chi_2$  for the fast and thermal groups, respectively.

\* An Input Region Data Block:

Repeated for each different material region;  $\max_k [\text{ITF}(k)]$  times.

Card Type 5: Format (I5)

k The consecutive mesh region number (counting from left to right) for identification purposes.

Card Types 6, 7: Format (3F10.5, 4E10.3, /, 30X, 3E10.3)

The geometry and nuclear constants for region k:

z(1) Beginning spatial coordinate of region k (cm)  
 z(2) Ending spatial coordinate of region k (cm)  
 H Width of region k (cm)  
 A(1) Fast-group macroscopic total cross section in region k ( $\text{cm}^{-1}$ )  
 F(1) Fast-group macroscopic production cross section,  $\nu\Sigma_f$ , in region k ( $\text{cm}^{-1}$ )  
 D(1) Fast-group diffusion coefficient in region k (cm)  
 S Fast-to-thermal macroscopic scattering cross section in region k ( $\text{cm}^{-1}$ )  
 A(2) Thermal-group macroscopic total cross section in region k ( $\text{cm}^{-1}$ )  
 F(2) Thermal-group macroscopic production cross section,  $\nu\Sigma_f$ , in region k ( $\text{cm}^{-1}$ )  
 D(2) Thermal-group diffusion coefficient in region k (cm)

\* End of an Input Region Data Block.

\*\* Power Method Input Block: Optional

Card Type 8: Format (F10.5)

$\omega$  Outer iteration overrelaxation parameter  $1 \leq \omega \leq 2$ .  
 Default is  $\omega = 1.25$ .

Card Type 9: Format (D25.14)

$\lambda^{(0)}$  Initial eigenvalue guess. Default is  $\lambda^{(0)} = 1.0$ .

Card Type 10: Format (4E20.10)

((F(g, i), i = 1 to N), g = 1 to 2) Initial group flux solution guess without zero flux boundary values. Default is  $\underline{F} = 1.0$ .

\*\* End of Power Method Input Block.

## B. Reference Solution Output Block

When IPUNCH = 1, REF2G punches out the number of fine mesh regions, KR, under Format (I5) followed by the converged flux solutions  $\psi(g, k)$  and corresponding current solutions  $\tilde{\eta}(g, k)$  for each group g and spatial node k including boundary conditions. When adjoint calculations are included, the results are punched out under Format (4D20.10), as

$$((\psi(g, k), \tilde{\eta}(g, k), \psi^*(g, k), \tilde{\eta}^*(g, k), k = 1 \text{ to } KR + 1), g = 1 \text{ to } 2)$$

where the notation denotes case reference solutions as well as detailed subassembly solutions. When the adjoint calculations have been bypassed, the results are punched out under Format (2D20.10) as

$$((\psi(g, k), \tilde{\eta}(g, k), k = 1 \text{ to } KR + 1), g = 1 \text{ to } 2)$$

A total of  $2 \text{ KR} + 3$  cards are punched out.

## D.2. Description of Program LINEAR

Program LINEAR forms and solves the difference equations resulting from the proposed approximation method using the linear basis functions. The program allows up to twenty-five coarse mesh regions, each of which is allowed to be broken into not more than one hundred homogeneous intervals. Combinations of both zero flux and

symmetry boundary conditions as well as use of the modified trial function forms in the boundary regions are allowed. Spatial flux and eigenvalue iteration history plots are also available.

The program allows a choice of the type of weighting, Galerkin or adjoint, to be used in the approximation. Also, either form of the detailed subassembly current solutions  $\eta_k(x)$  or  $\tilde{\eta}_k(x)$  is allowed. In addition, identical coarse mesh regions with identical detailed subassembly solutions can be repeated implicitly.

LINEAR also calculates results of the linear finite element method when suitable input is used. Such results can be obtained by using homogenized coarse mesh region nuclear constants and defining the detailed group flux solutions to be constant and the detailed currents to be zero (or by setting ITC = 0).

Punched results using detailed subassembly solutions constitute a Synthesis Method Output Block, while punched output resulting from the reduction to the finite element method with homogenized regional constants constitutes a Homogenized Method Output Block.

#### A. Homogenized or Synthesis Method Input Block

Undefined input parameters are identical to those previously defined in the REF2G input.

Card Type 1: Format (20A4)

An Appropriate Problem Title

Card Type 2: Format (2I5, 3E10.3, 6I5)

KR Total number of coarse mesh regions.  $KR \leq 25$ .

- IBC 1 - 4 As previously defined
- 5 Modified trial function (no tilting) in the first region, symmetry on the right
- 6 Zero flux on the left, modified trial function in the last region
- 7 Modified trial functions in both boundary regions
- EPS1
- EPS2
- EPS3
- IPLOT
- JPLOT
- IPUNCH
- ISEE
- ITW Type of approximation weighting desired:
- 0 Flux (Galerkin)
- 1 Adjoint
- ITC Form of the detailed current solutions in all sub-assemblies:
- 0  $\eta_k(x), \eta_k^*(x)$  as calculated by Fick's laws
- 1  $\tilde{\eta}_k(x), \tilde{\eta}_k^*(x)$  as given from REF2G output

Card Type 3: Format (25I2)

- ITF(k) The consecutive type-number of each coarse mesh region from left to right as  $k=1$  to  $KR$ . Allows for repeating identical subassemblies with no additional input.

Card Type 3 is repeated  $KR/25$  times (rounded off to the next highest integer).

Card Type 4: Format (2F10.5)

CHI(1), CHI(2)

\* An Input Subassembly Region Data Block:

Repeated for each different coarse mesh region;  $\max_k [\text{ITF}(k)]$   
times.

Card Type 5: Format (2I5)

- k The consecutive coarse mesh region number  
(from left to right).
- N The number of homogeneous intervals in sub-  
assembly k.  $N \leq 100$ .

Card Types 6, 7: Format (3F10.5, 4E10.3, /, 30X, 3E10.3)

The subassembly geometry and nuclear constants  
within each interval corresponding to the detailed  
subassembly solutions.

Repeated for each interval as  $i = 1$  to  $N$ :

- z(i) Beginning spatial coordinate of interval  $i$  (cm)
- z(i+1) Ending spatial coordinate of interval  $i$  (cm)
- H(i) Width of interval  $i$  (cm)
- A(1,i) Fast-group macroscopic total cross section in  
interval  $i$  ( $\text{cm}^{-1}$ )
- F(1,i) Fast-group macroscopic production cross section,  
 $\nu\Sigma_f$ , in interval  $i$  ( $\text{cm}^{-1}$ )
- D(1,i) Fast-group diffusion coefficient in interval  $i$  (cm)
- S(i) Fast-to-thermal macroscopic scattering cross  
section in interval  $i$  ( $\text{cm}^{-1}$ )
- A(2,i) Thermal-group macroscopic total cross section  
in interval  $i$  ( $\text{cm}^{-1}$ )
- F(2,i) Thermal-group macroscopic production cross  
section,  $\nu\Sigma_f$ , in interval  $i$  ( $\text{cm}^{-1}$ )
- D(2,i) Thermal-group diffusion coefficient in interval  $i$  (cm)

Card Type 8: Format (4D20.10)

The detailed subassembly solutions.

$$((\psi(g, k), \tilde{\eta}(g, k), \psi^*(g, k), \tilde{\eta}^*(g, k), k = 1 \text{ to } KR + 1), g = 1 \text{ to } 2)$$

A subassembly's Reference Solution Output Block without the first card.

\* END of an Input Subassembly Region Data Block.

\*\* Expected Solution Input Block: Optional

Card Type 9: Format (D25.14)

$\lambda_{\text{REF}}$  Expected eigenvalue solution. Default is  $\lambda_{\text{REF}} = 1.0$ .

Card Type 10: Format (4E20.10)

$((F(i, g), i = 1 \text{ to } N), g = 1 \text{ to } 2)$  Expected group flux solution without zero flux boundary values. Default is  $\underline{F} = 1.0$ .

\*\* END of the Expected Solution Input Block.

\*\*\* Power Method Input Block: Optional

As previously defined in the REF2G input.

\*\*\* END of the Power Method Input Block.

## B. Homogenized or Synthesis Method Output Block

When IPUNCH = 1, LINEAR punches out the total number of coarse mesh regions, KR, under Format (I5) followed by the resultant flux solutions including boundary conditions. The flux solutions are punched out under Format (2E20.7) as

$$(F(1, k), F(2, k), k = 1 \text{ to } KR + 1)$$

These cards represent either a Homogenized or Synthesis Method Output Block, depending upon the type and form of input data used.

### D.3 Description of Program CUBIC

Program CUBIC forms and solves the difference equations resulting from the proposed approximation method using the cubic Hermite basis functions. The program is very similar in form to program LINEAR and uses similar input.

#### A. Homogenized or Synthesis Method Input Block

The input to CUBIC is identical to that of LINEAR except for the following:

1. The boundary condition options are restricted by  $1 \leq \text{IBC} \leq 4$ .
2. The normalization constant  $\theta$  can be included on Card Type 4 after CHI(2) under Format (3F10.5). Default is  $\theta = 1.0$ .
3. Both the expected group solutions and the initial group solutions of the Expected Solution and Power Method Input Blocks, respectively, are of the form  $((F(g,i), i=1 \text{ to } N), g=1 \text{ to } 2)$  without either zero flux or zero current (or symmetry) boundary conditions. The solution vector is made up of alternating flux and current values as described in section 3.3 of Chapter 3. Default values are flux values of unity and current values of zero.

#### B. Homogenized or Synthesis Method Output Block

When IPUNCH = 1, CUBIC punches out the total number of coarse mesh regions, KR, under Format (I5) followed by the resultant flux and current solutions including boundary conditions. The solutions are punched out under Format (4E20.7) as

$$(F(1,k), F(2,k), G(1,k), G(2,k), k=1 \text{ to } KR+1)$$

where  $F(g,k)$  represents the flux, and  $G(g,k)$  the current solution of group  $g$  at node  $k$ .

As in the case of LINEAR, these KR+2 output cards represent either a Synthesis or Homogenized Method Output Block, depending upon the type and form of input data used.

#### D.4 Description of Program ANALYZE

ANALYZE compares the results of the reference solution, homogenized finite element method, and the proposed synthesis method for each case study where either linear or cubic Hermite basis functions have been used in the latter methods. For each of these three methods, the program first forms the complete detailed flux solution and then normalizes the flux distributions for each method such that their total power levels are unity. The fractional (normalized) power levels produced in each coarse mesh region are then calculated, compared, and listed. Finally, the detailed group fluxes of each method are plotted graphically relative to one another using the Stromberg-Carlson Computer Recorder, SC-4020, facility at M.I.T.<sup>54</sup> The graphic results for each group are normalized by the largest group-flux value such that the equivalent total power levels are preserved.

##### A. ANALYZE Input

The input to ANALYZE is read from five device units: 1, 2, 3, 11, 12, 13, and 5. Input and output data of the reference and approximation programs are read from the former six units while the standard input unit, 5, is reserved for SC-4020 plotting information.

The input is described by "Header Cards" and previously defined Input and Output Blocks. Header cards consist of one or more cards defined as follows:

Header Card 1: Format (4I5)

Method	Indicates the type of basis function approximation:
	1 Linear
	2 Cubic Hermite
NK	Total number of coarse mesh regions involved.
NR	Total number of fine mesh regions involved. NR = NK except for reference solution calculations.
NAP	Number of additional points to be plotted within each coarse mesh region. Used with the homogenized finite element method calculations. NAP < 0 denotes that the additional points are to be used in the first region (reflector) only.

Header Card 2: For use in device unit 3 input when NR ≠ NK.  
Format (16I5).

NRNK(k)	The number of fine mesh regions which make up each coarse mesh region k, as k = 1 to NK.
---------	--

The program is dimensioned to accept up to 200 fine mesh regions (or intervals) per coarse mesh region, up to 25 coarse mesh regions, and up to a grand total of 1000 fine mesh regions in each case study.

The form of the ANALYZE input is given as follows:

Input Data for Unit 1:

Header Cards

[ Homogenized Method Input Block ]

Input Data for Unit 2:

Header Cards

[ Synthesis Method Input Block ]

Input Data for Unit 3:

Header Cards

[ Reference Solution Input Block ]

Input Data for Unit 11:

[ Homogenized Method Output Block ]

Input Data for Unit 12:

[ Synthesis Method Output Block ]

Input Data for Unit 13:

[ Reference Solution Output Block ]

Input Data for Unit 5:

No SC-4020 plots are generated if this data is omitted.

Card 1: Format (20A4)

An appropriate title written above each plotted graph.

Card 2: Format (2F10.5)

XINCH Total width of the graph in inches including labels  
(limited to 7.45").

YINCH Total height of the graph in inches including labels  
(limited to 7.45").

Card 3: Format (I10, F10.5)

NCELL Total number of coarse mesh regions.  $NCELL \leq 25$ .  
( $NCELL < 0$  indicates that the last region is of width  
 $\frac{1}{2}$  WCELL.)

WCELL Width of each coarse mesh region in cm.

Card 4: Optional. Format (I10, 7F10.5)

NLL Number of vertical light lines to be added to the plotted  
graphs.  $NLL \leq 100$ .

XL(i) Spatial location (cm) of the light lines;  $i = 1$  to 7.

Card 5: Format (8F10.5)

XL(i) As above when  $NLL > 7$ .

## Appendix E

SAMPLE INPUT AND OUTPUT DATA BLOCKS  
FOR PROGRAMS REF2G, LINEAR, CUBIC, AND ANALYZE

SUBROUTINE PRTPLOT(NO,B,N,M,NL,NS,KX,JX,ISP)
C*****MODIFIED VERSION FROM THAT OF SSP OR ANY OTHER SOURCE *****
C      CONVERTS DOUBLE PRECISION B ARRAY TO REAL*4.
C      PLOT SEVERAL CROSS-VARIABLES VERSUS A BASE VARIABLE
C      NO - CHART NUMBER (3 DIGITS MAXIMUM)
C      B - MATRIX OF DATA TO BE PLOTTED. FIRST COLUMN REPRESENTS
C      BASE VARIABLE AND SUCCESSIVE COLUMNS ARE THE CROSS-
C      VARIABLES (MAXIMUM IS 9).
C      N - NUMBER OF ROWS IN MATRIX B
C      M - NUMBER OF COLUMNS IN MATRIX B (EQUAL TO THE TOTAL
C      NUMBER OF VARIABLES). MAXIMUM IS 10.
C      NL - NUMBER OF LINES IN THE PLOT. IF 0 IS SPECIFIED, 50
C      LINES ARE USED. THE NUMBER OF LINES MUST BE EQUAL TO
C      OR GREATER THAN N
C      (USUALLY USE NL=N, AND ISP FOR SPACING.)
C      NS - CODE FOR SORTING THE BASE VARIABLE DATA IN ASCENDING
C      ORDER
C          0 SORTING IS NOT NECESSARY (ALREADY IN ASCENDING
C          ORDER).
C          1 SORTING IS NECESSARY.
C      KX- DIMENSION OF B MATRIX FROM DIMENSION STATEMENT.
C      IT MUST BE OF THE FORM B(KX,JX)
C      JX- DIMENSION OF B MATRIX FROM DIMENSION STATEMENT.
C      IT MUST BE OF THE FORM B(KX,JX)
C      ISP- CODE FOR SPACING LINES WHILE PLOTTING:
C          1 SINGLE SPACE
C          2 DOUBLE SPACE
C          3 TRIPLE SPACE
C          ...ETC.
